// Error with additional data

```
JsonRpcError
Standard JSON-RPC error structure.
```

```
pub struct JsonRpcError {
```

```
 Standard Error Codes:
 - `~32700`: Parse error
 - `~32600`: Invalid request
 - `~32601`: Method not found
 - `~32602`: Invalid params
 - `~32603`: Internal error
 - `~32000 to ~32099`: Server-defined errors
```

```
JsonRpcServer
Async JSON-RPC server over Unix sockets.
```

```
pub struct JsonRpcServer {
```

```
 Key Methods:
 - `new(socket_path)`: Create server bound to Unix socket
 - `register_method(name, handler)`: Register RPC method handler
 - `run()`: Start server event loop
 - `shutdown()`: Graceful shutdown
```

```
OvsdbClient
Client for Open vSwitch database operations.
```

```
pub struct OvsdbClient {
```

```
 Key Operations:
 - `connect(socket)`: Connect to OVSDB server
 - `list_dbs()`: List available databases
 - `get_schema(db)`: Retrieve database schema
 - `transact(operations)`: Execute transactional operations
 - `monitor(db, tables)`: Subscribe to table updates
```

```
NonNetDb
Database for non-network plugin state.
```

```
pub struct NonNetDb {
```

```
 Key Operations:
 - `new(path)`: Create/open database at path
 - `get(key)`: Retrieve value by key
 - `set(key, value)`: Store key-value pair
 - `delete(key)`: Remove key
 - `list()`: List all keys
 - `query(filter)`: Query with filter criteria
```

```
Module Structure
```

```
Core Modules
- **protocol**: JSON-RPC 2.0 message types and builders
```

## OP-DBUS / BigPickle

```
- **server**: Unix socket server implementation
- **ovsdb**: OVSDb client and operations
- **nonnet**: NonNet database implementation

Supporting Modules
- **ovsdb_jsonrpc**: OVSDb-specific JSON-RPC extensions
- **nonnet_staging**: Staging area for NonNet operations

Dependencies

Core Dependencies
- **op-core**: Core types and utilities
- **tokio**: Async runtime and I/O
- **serde**: Serialization framework
- **simd-json**: High-performance JSON parsing
- **uuid**: Request ID generation

Error Handling
- **anyhow**: Flexible error handling
- **thiserror**: Custom error types

Logging
- **tracing**: Structured logging and diagnostics

Usage

Starting a JSON-RPC Server
```

```
use op_jsonrpc::{JsonRpcServer, JsonRpcRequest, JsonRpcResponse};
```

```
#[tokio::main]
```

```
// Register method handler
```

```
// Run server
```

```
Ok()
```

```
OVSDb Integration
```

```
use op_jsonrpc::OvsdbClient;
```

```
// Connect to OVSDb
```

```
// List databases
```

```
// Get schema
```

```
// Execute transaction
```

```
NonNet Database Operations
```

```
use op_jsonrpc::NonNetDb;
```

```
// Open database
```

```
// Store plugin state
```

```
// Retrieve state
```

```
// Query with filter
```

```
Method Registration
```

```
// Register multiple methods
```

```
server.register_method("get_status", |req| async move {
```

```
Protocol Compliance
```

```
JSON-RPC 2.0 Specification
```

### OVSDb Protocol

## Integration Points

### Operation-DBUS Architecture

### D-Bus Services

### Plugin Communication

Plugins communicate with core services via JSON-RPC:

1. Plugin connects to Unix socket
2. Sends JSON-RPC requests
3. Receives responses
4. Handles notifications

### Network Configuration

OVSDb integration enables:

- Bridge creation and management
- Port configuration
- Flow table operations
- Network topology queries

## Performance Considerations

### JSON Parsing

- **\*\*simd-json\*\***: SIMD-accelerated parsing for high throughput
- **\*\*Zero-copy\*\***: Minimize allocations where possible

### Connection Handling

- **\*\*Async I/O\*\***: Non-blocking operations via tokio
- **\*\*Connection Pooling\*\***: Reuse connections to OVSDb
- **\*\*Backpressure\*\***: Handle slow clients gracefully

### Database Operations

- **\*\*Batching\*\***: Group NonNet operations for efficiency
- **\*\*Caching\*\***: Cache frequently accessed state
- **\*\*Indexing\*\***: Optimize query performance

## Error Handling

### Protocol Errors

- Parse errors (malformed JSON)
- Invalid request structure
- Method not found
- Invalid parameters

### Database Errors

- OVSDb connection failures
- Transaction conflicts
- NonNet storage errors
- Schema validation failures

### Recovery Strategies

- Automatic reconnection to OVSDb
- Transaction retry with backoff
- Graceful degradation on errors
- Detailed error logging

## Testing

### Unit Tests

- Protocol message serialization
- Error response generation
- Method routing logic

### Integration Tests

- End-to-end RPC communication
- OVSDb transaction handling
- NonNet database operations

### Mock Support

- Mock OVSDb server for testing
- In-memory NonNet database
- Simulated network conditions

```
Security Considerations

Unix Socket Permissions
- Restrict socket file permissions
- Validate client credentials
- Rate limiting per connection

Input Validation
- Validate all RPC parameters
- Sanitize database queries
- Prevent injection attacks

OVSDB Security
- Secure connection to OVSDB
- Validate transaction operations
- Audit database modifications

Future Enhancements

- **WebSocket Transport**: Support WebSocket in addition to Unix sockets
- **TLS Support**: Encrypted RPC communication
- **Authentication**: Client authentication and authorization
- **Batch Optimization**: Parallel batch request processing
- **Metrics**: Prometheus metrics for RPC operations
- **Tracing**: Distributed tracing integration
- **Schema Validation**: Automatic parameter validation from schemas
- **Code Generation**: Generate client stubs from method definitions

Related Crates

- **op-core**: Core types and utilities
- **op-network**: Network configuration using OVSDB
- **op-plugins**: Plugin system using JSON-RPC
- **op-services**: Service management via RPC

JSON-RPC 2.0 server with OVSDB and NonNet database support

//! Antigravity Replay Provider
//!
//! Uses captured Antigravity IDE session (OAuth token + headers) to make
//! API requests that appear to come from the IDE.
//!
//! This allows op-dbus to leverage Code Assist enterprise subscriptions.
//!
//! ## Setup
//!
//! 1. Run `antigravity-proxy-capture.sh` to capture IDE credentials
//! 2. Set `ANTIGRAVITY_SESSION_FILE` environment variable
//! 3. Use `LLM_PROVIDER=antigravity_replay`
//!
//! ## How It Works
//!
//! The Antigravity IDE sends specific headers that identify it as an IDE client:
//! - X-Goog-API-Client: contains IDE version info
//! - User-Agent: identifies as Antigravity
//! - Other proprietary headers
//!
//! By capturing and replaying these headers along with the OAuth token,
//! our requests appear to come from the IDE and get Code Assist benefits.

 //! Gemini CLI Integration via PTY Bridge
 //!
 //! Uses the PTY bridge to run `gemini` CLI tool on headless servers,
 //! handling OAuth authentication flows transparently.
 //!
 //! ## Prerequisites
 //!
 //! Install Gemini CLI:
 //! ```bash
 //! npm install -g @google/gemini-cli
 //! ```
 //!
 //! ## How Auth Works

```

```

//!
//! This provider uses gcloud credentials:
//! 1. Set up gcloud auth: `gcloud auth login`
//! 2. Or use service account: Set `GOOGLE_APPLICATION_CREDENTIALS` env var
//! 3. PTY bridge passes credentials to Gemini CLI automatically
//! 4. Gemini CLI uses gcloud credentials for API calls

 //! Google Gemini API Client
 //!
 //! ## Supported Authentication Modes
 //!
 //! ### 1. Service Account (Vertex AI) - Recommended for servers
 //! Uses service account JSON file for JWT-based authentication.
 //! Set environment variable:
 //! - `GOOGLE_APPLICATION_CREDENTIALS=/path/to/service-account.json`
 //! - Or uses default: `~/.config/gcloud/*.json` (service account file)
 //!
 //! ### 2. Application Default Credentials (OAuth refresh token)
 //! Uses `~/.config/gcloud/application_default_credentials.json`
 //! Set environment variable:
 //! - `GOOGLE_GENAI_USE_VERTEXAI=true`
 //!
 //! ### 3. API Key (generativelanguage.googleapis.com)
 //! Uses API key authentication with Google AI Studio endpoint.
 //! Set environment variable:
 //! - `GEMINI_API_KEY` or `GOOGLE_API_KEY`
 //!
 //! ## Endpoint URLs
 //!
 //! | Mode | Base URL |
 //! |-----|-----|
 //! | Vertex AI | `https://{LOCATION}-aiplatform.googleapis.com/v1/projects/{PROJECT}/locations/{LOCATION}/publishers/google/model`
 //! | API Key | `https://generativelanguage.googleapis.com/v1beta/models` |

///! PTY Authentication Bridge
///!
///! Wraps CLI tools in a pseudo-terminal to handle interactive authentication
///! flows on headless servers.
///!
///! ## Use Cases
///!
///! - Running `gemini` CLI on servers without browsers
///! - Using `gh` (GitHub CLI) device code flow
///! - Any CLI tool with interactive OAuth
///!
///! ## How It Works
///!
///! 1. Spawn the CLI in a PTY (pseudo-terminal)
///! 2. Monitor output for auth patterns (URLs, device codes, prompts)
///! 3. When auth is detected, emit notification (webhook, D-Bus signal, web UI)
///! 4. User completes auth on their device
///! 5. Bridge detects completion and continues execution

Current Implementation Overview

- LLM provider integration with dynamic model discovery for HuggingFace

Module / File Comparison

| Module or File | State | Current Role | Notes |
|---|---|---|---|

Feature / Capability Comparison

| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
- None

External Runtime Dependencies
- `tokio` - documented in SPEC
- `serde` - documented in SPEC
- `simd-json` - documented in SPEC
- `anyhow` - documented in SPEC
- `thiserror` - documented in SPEC
- `tracing` - documented in SPEC
- `async-trait` - documented in SPEC
- `reqwest` - documented in SPEC
- `chrono` - documented in SPEC
- `rsa` - documented in SPEC
- `sha2.workspace` - documented in SPEC
- `base64.workspace` - documented in SPEC
- `jsonwebtoken` - documented in SPEC
- `uuid` - documented in SPEC
- `dirs` - documented in SPEC

Development and Build Dependencies
- None

Notes and Observations

- Local documentation files present: SPEC.md.
- Current implementation contains 1 Rust source files beyond the explicit spec/design source inventory.
- Root module declarations found in `lib.rs`/`main.rs`: anthropic, antigravity, chat, gcloud_adc, gemini, gemini_cli, headless_oau
</file>

op-mcp Architecture

Overview

op-mcp is a clean MCP (Model Context Protocol) server that provides:

1. **MCP JSON-RPC 2.0 Protocol** - Standard MCP protocol over stdio
2. **Lazy Tool Loading** - Tools loaded on-demand with LRU caching
3. **Discovery System** - Multiple sources for tool discovery
4. **External MCP Aggregation** - Connect to other MCP servers

Architecture Diagram
```

## Key Components

### 1. McpServer

The main server component that:

- Handles MCP JSON-RPC 2.0 protocol

```
- Routes requests to appropriate handlers
- Manages server lifecycle

2. LazyToolManager

Manages tool loading with:
- **On-demand loading**: Tools loaded when first requested
- **LRU caching**: Evicts unused tools to save memory
- **Context filtering**: Returns relevant tools based on context
- **Multiple sources**: D-Bus, plugins, agents, external MCP

3. ToolRegistry (from op-tools)

Provides:
- Tool storage with usage tracking
- LRU eviction policy
- Factory-based lazy loading
- Statistics and monitoring

4. ToolDiscoverySystem (from op-tools)

Manages tool discovery from:
- **BuiltinToolSource**: Compiled-in tools
- **DbusDiscoverySource**: Runtime D-Bus introspection
- **PluginDiscoverySource**: State management plugins
- **AgentDiscoverySource**: Agent-based tools

Data Flow

Tool Listing
```

Apply context filter

### Tool Execution

Tool.execute(args)

```
Configuration

Environment Variables

| Variable | Default | Description |
|-----|-----|-----|
| `MCP_MAX_TOOLS` | 50 | Max tools to keep loaded |
| `MCP_IDLE_SECS` | 300 | Idle time before eviction |
| `MCP_DBUS_DISCOVERY` | true | Enable D-Bus discovery |
| `MCP_PLUGIN_DISCOVERY` | true | Enable plugin discovery |
| `MCP_AGENT_DISCOVERY` | true | Enable agent discovery |
| `MCP_PRELOAD` | true | Preload essential tools |

Benefits

1. **Memory Efficient**: Only loads tools when needed
2. **Fast Startup**: No upfront tool loading
3. **Scalable**: Supports thousands of tools
4. **Context-Aware**: Returns relevant tools based on context
5. **Extensible**: Easy to add new discovery sources

 //! Agents MCP Server - D-Bus First Architecture
 //!

```

## OP-DBUS / BigPickle

```
///! Discovers agents via D-Bus introspection and exposes them as MCP tools.
///! This is the proper architecture for Project D-Bus.
///!
///! ## How It Works
///!
///! 1. Agent Manager starts agents as D-Bus services
///! - org.dbusmcp.Agent.RustPro
///! - org.dbusmcp.Agent.PythonPro
///! - etc.
///!
///! 2. This server uses introspection to discover running agents
///! - Lists services matching org.dbusmcp.Agent.*
///! - Introspects each to get methods/properties
///!
///! 3. Exposes discovered agents as MCP tools
///! - rust_pro_check, rust_pro_build, etc.
///!
///! 4. Tool calls are proxied to D-Bus
///! - MCP tool call -> D-Bus method call -> Agent execution
```

Overview

op-mcp is a unified MCP (Model Context Protocol) server supporting multiple transports:

- **Stdio**: Standard input/output for CLI integration
- **HTTP**: REST endpoints with SSE support
- **WebSocket**: Full-duplex communication
- **gRPC**: High-performance RPC (optional)

Components

McpServer
Core server handling all MCP protocol logic. Transport-agnostic.

Transport Layer
Abstract `Transport` trait with implementations for each protocol.

Tool System
`ToolExecutor` trait allows pluggable tool backends.

Configuration

| Option | Default | Description |
|-----|-----|-----|
| `compact_mode` | false | Use 5 lazy meta-tools instead of all |
| `max_tools` | 500 | Maximum tools to expose |
| `blocked_patterns` | [...] | Tool patterns to block |
";
</file>

- `clap` - not listed in SPEC dependency block
- `tonic` - not listed in SPEC dependency block
- `prost` - not listed in SPEC dependency block

Development and Build Dependencies
- `build:tonic-build`

Notes and Observations

- Local documentation files present: README.md, SPEC.md, docs/ARCHITECTURE.md.
- Transitional or partial artifacts detected: src/agents_server.rs.patch, src/mod.rs.patch.
- Current implementation contains 21 Rust source files beyond the explicit spec/design source inventory.
- Root module declarations found in `lib.rs`/`main.rs`: agents_server, compact, protocol, resources, server, transport, tool_regis
- Cargo feature flags: default, grpc.
- RPC or protocol definition files: proto/internal_agents.proto, proto/mcp.proto.
- 11 runtime dependencies are present in `Cargo.toml` but omitted from the SPEC dependency block.
</file>

<file path="op-mcp/README.md">
op-mcp: Minimal MCP Protocol Adapter

Architecture

This is a thin protocol adapter that exposes op-dbus-v2 functionality via the Model Context Protocol (MCP). It delegates all i

- op-chat - Orchestration and LLM integration
- op-tools - Tool registry and execution
- op-introspection - D-Bus discovery and scanning

Design Principle

op-mcp = Protocol Adapter ONLY

All complex functionality already exists in other crates. This crate just translates between:
- MCP JSON-RPC protocol (stdin/stdout)
- op-chat RPC calls

Protocol Flow

Supported Methods

- `initialize` - MCP handshake and capabilities
- `resources/list` - List documentation resources (placeholder)
- `resources/read` - Read documentation (placeholder)

Code Size

- Before: ~20,000 lines (95% duplication)
- After: ~350 lines (protocol adapter only)
- Reduction: 98% smaller!

Building and Running
```

## Build the MCP server

```
cargo build --package op-mcp
```

## Run as MCP server

```
./target/debug/op-mcp-server
```

## Or install and run

```
cargo install --package op-mcp
```

```
Dependencies

Minimal dependency set:
- `op-chat` - For orchestration
- `op-core` - For core types
- `tokio` - Async runtime
- `serde` - JSON serialization
- Standard logging/tracing crates

No duplicate implementations of:
- Tool registries
- Introspection systems
- Orchestrators
- Chat systems

Integration

The MCP server integrates seamlessly with:

1. **Claude Desktop** - Add to MCP config:
  ```json
  {
    "mcpServers": {
      "op-dbus-v2": {
        "command": "op-mcp-server",
        "args": []
      }
    }
  }
  ```

2. **Other MCP Clients** - Any client that supports stdio-based MCP servers

Error Handling

- Proper JSON-RPC 2.0 error responses
- Graceful handling of malformed requests
- Detailed error messages for debugging
- Protocol version compliance

Testing

The minimal design makes testing straightforward:

- Unit tests for protocol translation
- Integration tests with op-chat
- Protocol compliance tests

Future Extensions

If needed, this can be extended with:
- Resource registry with embedded documentation
- Additional MCP protocol features
- Health checking and monitoring
- Configuration management

Migration from Old Implementation
```

The old implementation (`op-mcp.backup`) had massive duplication:

- Tool registry (use `op-tools`)
  - Introspection system (use `op-introspection`)
  - Chat orchestration (use `op-chat`)
  - Agent management (use `op-agents`)
  - Multiple web bridges
  - Workflow systems
- 
- MCP JSON-RPC protocol handling
  - Request/response translation
  - Resource serving (placeholder)

## Benefits

1. **Maintainable**: 350 lines vs 20,000 lines
2. **No Duplication**: Each feature exists in ONE place
3. **Clear Architecture**: Single responsibility principle
4. **Easy Testing**: Simple, focused components
5. **Protocol Compliant**: Proper MCP implementation

## Contributing

Keep it simple:

1. If you need new functionality, add it to the appropriate base crate
2. If you need MCP protocol features, add them here
3. Always delegate to existing crates - never duplicate

/// Context-Aware Tool Loading
///
/// Dynamically suggests and enables tool groups based on conversation context.
/// This bridges Compact Mode (lazy loading) with Tool Groups (domain organization).
///
/// ## How It Works
///
/// 1. **Analyze Context**: Extract signals from messages, files, commands
/// 2. **Match Groups**: Map context signals to relevant tool groups
/// 3. **Suggest/Auto-Enable**: Recommend or auto-enable groups within limit
///
/// ## Context Signals

 /// Compact Mode - Reduces 750+ tools to 4-5 meta-tools
 ///
 /// Instead of exposing every tool directly (which consumes massive context window),
 /// compact mode exposes just a few meta-tools:
 ///
 /// 1. `list_tools` - List available tools with filtering
 /// 2. `execute_tool` - Execute any tool by name
 /// 3. `get_tool_schema` - Get schema for a specific tool
 /// 4. `search_tools` - Search tools by keyword
 ///
 /// This design:
 /// - Saves ~95% of context tokens
 /// - Bypasses Cursor's 40-tool limit entirely
 /// - Keeps all tools accessible via execute_tool
 /// - Improves LLM reasoning (fewer choices = better decisions)

 //! Tool Groups - Granular, domain-specific tool sets
 //!
 //! Groups are designed to be ~5 tools each for flexibility.
 //! Mix and match to create custom configurations under any limit.
 //!
 //! ## Security Levels
 //!
 //! | Level | Description | API Key Required |
 //! |-----|-----|-----|
 //! | public | Safe read-only tools | No |
 //! | standard | Normal operations | No |
 //! | elevated | System modifications | Optional |
 //! | restricted | Dangerous commands | **YES** |
 //!
 //! ## Domain Groups
 //!
 //! - **Core**: Essential tools (respond, info)
 //! - **DevOps**: Infrastructure, deployment
 //! - **Security**: Auth, SSO, secrets
 //! - **Business**: Marketing, HR, analytics
 //! - **System**: Restricted admin commands

<file path="op-mcp-aggregator/src/lib.rs">
 //! op-mcp-aggregator: MCP Server Aggregator
 //!
 //! This crate provides an aggregator that proxies multiple upstream MCP servers,
 //! presenting a unified tool interface while staying under Cursor's 40-tool limit.
 //!
 //! ## Modes
 //!
 //! ### Full Mode (Traditional)
 //! Exposes all tools directly. Good for small tool sets (<40 tools).
 //!
 //! ### Compact Mode (Recommended)
 //! Reduces 750+ tools to 4-5 meta-tools:
 //! - `list_tools` - Browse available tools
 //! - `search_tools` - Find tools by keyword
 //! - `get_tool_schema` - Get input schema for a tool
 //! - `execute_tool` - Execute any tool by name
 //!
 //! Benefits:
 //! - ~95% context token savings
 //! - Bypasses 40-tool limit entirely
 //! - Works with Cursor, Gemini CLI, and any MCP client
 //! - All tools remain accessible via execute_tool
 //!
 //! ## Architecture
 //!
 //! ```text
 //! ```
 //!
 //! ## Usage
 //!
 //! ```rust,ignore
 //! use op_mcp_aggregator::{Aggregator, AggregatorConfig, ToolMode};
 //!
 //! let config = AggregatorConfig::load("/etc/op-dbus/aggregator.json");
 //! let aggregator = Aggregator::new(config).await?;
 //! aggregator.initialize().await?;
 //!
 //! // Get MCP tools (compact mode returns 4 meta-tools)
 //! let mcp_tools = aggregator.get_mcp_tools(ToolMode::Compact).await?;
 //!
 //! // Or use full mode for direct tool access
 //! let all_tools = aggregator.get_mcp_tools(ToolMode::Full).await?;
 //! ```

<file path="op-mcp-aggregator/CLEANUP-CONTEXT-AWARE.md">
Context-Aware Code Cleanup

Summary

Removed unused context-aware tool loading code from `op-mcp-aggregator` since the project uses the simpler compact mode implementa

What Was Removed

Files Moved to `crates/op-mcp-aggregator/src/unused/`:

1. **`context.rs`** (632 lines)
 - Context-aware tool suggestion system
 - Analyzed conversation context (files, keywords, commands, intent)
 - Auto-enabled relevant tool groups based on confidence scores
 - **Why unused**: Compact mode doesn't need context analysis - it exposes all tools via meta-tools

2. **`groups.rs`** (likely similar size)
 - Tool group management and organization
 - Security levels and access zones
 - Network-based tool filtering
 - **Why unused**: Compact mode doesn't organize tools into groups - it provides search/execute instead

Code Removed from `lib.rs`:
```

// Removed module declarations

// Removed re-exports

```
Why This Was Safe

1. **No imports found**: Searched entire codebase - no files import these modules
2. **Different architecture**: `op-web` uses its own compact mode implementation
3. **Simpler is better**: Compact mode (4 meta-tools) is more effective than context-aware groups (still limited to 40 tools)

The Two Approaches

Context-Aware (Removed)

Compact Mode (Current)

Performance Impact

Before: ~1000 lines of unused context-aware code
After: Clean, focused codebase
```

```
Build time: Slightly faster (less code to compile)
Runtime: No change (code wasn't being called anyway)

Recovery

If you ever want to restore the context-aware code:
```

```
mv crates/op-mcp-aggregator/src/unused/*.rs crates/op-mcp-aggregator/src/
```

```
Recommendation

Keep using compact mode. It's simpler, more powerful, and actually works with your current setup.

Spec-listed source files	9
Spec-listed but missing	0
Extra implementation files	0

Current Implementation Overview

- MCP Server Aggregator - proxies and aggregates multiple MCP servers behind a single endpoint
- Internal crate integrations: op-core, op-tools, op-plugins.

Module / File Comparison

Module or File	State	Current Role	Notes

Feature / Capability Comparison

Capability	State	Evidence	Source

Dependencies Comparison

Internal Workspace Dependencies
- `op-core` - documented in SPEC
- `op-tools` - documented in SPEC
- `op-plugins` - documented in SPEC

External Runtime Dependencies
- `tokio` - documented in SPEC
- `futures` - documented in SPEC
- `async-trait` - documented in SPEC
- `serde` - documented in SPEC
- `simd-json` - documented in SPEC
- `serde_yaml` - documented in SPEC
- `request` - documented in SPEC
- `anyhow` - documented in SPEC
- `thiserror` - not listed in SPEC dependency block
- `tracing` - not listed in SPEC dependency block
```

```
- `uuid` - not listed in SPEC dependency block
- `chrono` - not listed in SPEC dependency block
- `lru` - not listed in SPEC dependency block
- `base64` - not listed in SPEC dependency block

Development and Build Dependencies
- `dev:tokio-test`

Notes and Observations

- Local documentation files present: CLEANUP-CONTEXT-AWARE.md, README.md, SPEC.md.
- Transitional or partial artifacts detected: src/groups.rs.patch.
- Root module declarations found in `lib.rs`/`main.rs`: aggregator, cache, client, compact, config, groups, profile.
- 6 runtime dependencies are present in `Cargo.toml` but omitted from the SPEC dependency block.
</file>

<file path="op-mcp-aggregator/README.md">
op-mcp-aggregator

MCP Server Aggregator - proxies and aggregates multiple MCP servers behind a single endpoint, with intelligent tool management to

Features

Feature	Description
Compact Mode	Reduces 750+ tools to 4 meta-tools (~95% context savings)
Tool Groups	Organize tools into toggleable sets (systemd, network, etc.)
Profiles	Named configurations for different use cases
Multi-Server	Aggregate tools from unlimited upstream MCP servers

Problem

Cursor IDE has a hard limit of ~40 MCP tools. If you have multiple MCP servers or a server with many tools, you quickly hit this l

Solutions

1. Compact Mode (Recommended for LLMs)

Exposes only 4 meta-tools instead of hundreds:
- `list_tools` - Browse available tools
- `search_tools` - Find tools by keyword
- `get_tool_schema` - Get input schema
- `execute_tool` - Run any tool

Auto-enabled for: Gemini CLI, Claude, ChatGPT, any LLM client

2. Tool Groups (For Full Mode)

Organize tools into toggleable sets:

Group	Description	~Tools
core	Essential (respond, system_info)	5
shell	Command execution	3
filesystem	File operations	10
systemd	Service management	12
network	Network config	10
dbus	D-Bus introspection	8
packages	Package management	6
monitoring	System metrics	8
git	Version control	10

Example: Enable `core + shell + systemd + network = 30 tools` (under 40!)

This crate provides an **aggregator** that:

1. **Connects to multiple upstream MCP servers** (SSE, stdio, websocket)
2. **Caches tool schemas** with TTL and LRU eviction
3. **Provides named profiles** that select subsets of tools
4. **Routes tool calls** to the correct upstream server
5. **Stays under Cursor's limits** per-profile

Architecture
```

```
Configuration

Create `etc/op-dbus/aggregator.json`:

{

Usage

In Cursor

Update `~/.cursor/mcp.json`:

{

Switch profiles by changing the URL path:
- `mcp/profile/sysadmin` - System admin tools
- `mcp/profile/dev` - Development tools
- `mcp/profile/minimal` - Essential tools only

Programmatic

use op_mcp_aggregator::{Aggregator, AggregatorConfig};

#[tokio::main]

// Create and initialize aggregator

// List tools for a profile

// Call a tool

Ok()

Server Configuration

Server Options

Field	Type	Description
`id`	string	Unique identifier
`name`	string	Human-readable name
`url`	string	Server URL or command
`transport`	`sse`/`stdio`/`websocket`	Connection type
`enabled`	bool	Whether to use this server
`tool_prefix`	string?	Prefix added to tool names
`include_tools`	string[]	Only include these tools
`exclude_tools`	string[]	Exclude these tools
`priority`	int	Higher = preferred when tools conflict
`timeout_secs`	int	Connection timeout
`auth`	object?	Authentication config

Profile Options

Field	Type	Description
`description`	string	Human-readable description
`servers`	string[]	Which servers to include
`include_tools`	string[]	Specific tools (supports `*` wildcard)
`exclude_tools`	string[]	Tools to exclude
`include_categories`	string[]	Tool categories to include
`include_namespaces`	string[]	Namespaces to include
`max_tools`	int?	Max tools for this profile

Features

- **Multi-server aggregation**: Connect to unlimited upstream MCP servers
- **Profile-based filtering**: Define named profiles with different tool sets
- **Wildcard support**: Use `github_*` to match tool names
- **Tool prefixing**: Avoid name collisions with prefixes like `github_search`
- **LRU caching**: Efficient tool schema caching with TTL
- **Background refresh**: Keep schemas fresh automatically
```

```
- **Health checks**: Monitor upstream server status
- **Auth support**: Bearer tokens, basic auth, custom headers
- **Environment variables**: Use `${VAR_NAME}` in config values

Integration with op-mcp

The aggregator integrates seamlessly with `op-mcp`. Add upstream servers and profiles to your existing setup without changing how

Date: 2026-04-05
Spec files analyzed: SPEC.md
Analysis mode: Current system state specification with spec-alignment notes

Summary

Category	Count
Rust source files	5
Proto files	0
Binary targets	0
UI files	0
Root-declared modules	4
Partial artifacts	0
Spec-listed source files	0
Spec-listed but missing	0
Extra implementation files	5

Current Implementation Overview

- ML/Embedding support: model management, text embedder, vector storage

Module / File Comparison

Module or File	State	Current Role	Notes

Feature / Capability Comparison

Capability	State	Evidence	Source

Dependencies Comparison

Internal Workspace Dependencies
- None

External Runtime Dependencies
- `tokio` - not listed in SPEC dependency block
- `serde` - not listed in SPEC dependency block
- `simd-json` - not listed in SPEC dependency block
- `anyhow` - not listed in SPEC dependency block
- `thiserror` - not listed in SPEC dependency block
- `tracing` - not listed in SPEC dependency block
- `request` - not listed in SPEC dependency block
- `log` - not listed in SPEC dependency block
- `num_cpus` - not listed in SPEC dependency block
- `sha2` - not listed in SPEC dependency block

Development and Build Dependencies
- None

Notes and Observations

- Local documentation files present: SPEC.md.
- Current implementation contains 5 Rust source files beyond the explicit spec/design source inventory.
- Root module declarations found in `lib.rs`/`main.rs`: config, downloader, embedder, model_manager.
- Cargo feature flags: default, ml.

op-ml - Specification

Overview
Crate: `op-ml`
Location: `crates/op-ml`
Description: ML/Embedding support: model management, text embedder, vector storage
```

```
Purpose

The `op-ml` crate provides machine learning capabilities for the operation-dbus system, with a focus on text embeddings and semantic search.

Key capabilities:
- Text Embeddings: Convert text to high-dimensional vectors for semantic similarity
- Model Management: Automatic model downloading and caching
- Multi-Backend Support: CPU, NVIDIA GPU, Apple Neural Engine, Windows DirectML
- Lazy Loading: Models loaded on-demand to minimize startup overhead
- Configurable Quality: Fast, balanced, and best quality embedding models

This crate enables:
- Semantic search across D-Bus interfaces and documentation
- Intelligent plugin discovery based on natural language queries
- Context-aware agent routing
- Vector-based similarity matching

Architecture

Lazy Loading Design
Models are loaded on first use to avoid startup penalties:
1. Application starts with minimal overhead
2. First embedding request triggers model download/load
3. Subsequent requests use cached model
4. Global singleton ensures single model instance

Execution Providers
Supports multiple hardware acceleration backends:
- CPU: Multi-threaded inference with configurable thread count
- CUDA: NVIDIA GPU acceleration
- TensorRT: Optimized NVIDIA inference
- DirectML: Windows GPU acceleration
- CoreML: Apple Neural Engine and GPU

Model Tiers
Three quality levels balancing speed vs accuracy:

Level	Model	Dimensions	Speed	Use Case
Fast	MiniLM-L6	384	Fastest	Real-time queries
Balanced	MiniLM-L12	384	Medium	General purpose
Best	BGE-Base	768	Slower	High accuracy needs

Key Components

ModelManager
Central component for model lifecycle management.
```

```
pub struct ModelManager {

Key Methods:

// Create new manager with config
// Get global singleton instance
// Check if ML is enabled
// Embed single text
// Embed batch of texts

Singleton Pattern:

static MODEL_MANAGER: OnceCell<Arc<ModelManager>> = OnceCell::new();

TextEmbedder
ONNX Runtime-based text embedding engine.

pub struct TextEmbedder {

Key Methods:
```

## OP-DBUS / BigPickle

// Load model from directory

// Embed text to vector

// Embed batch

```
ModelDownloader
Automatic model downloading and caching.
```

```
pub struct ModelDownloader {
```

```
Key Methods:
```

// Create downloader with cache directory

// Download model if not cached

// Check if model is cached

// Get model directory path

```
Download Sources:
```

- HuggingFace model hub
- Local mirror support
- Checksum verification with SHA256

```
VectorizationConfig
Configuration for embedding behavior.
```

```
pub struct VectorizationConfig {
```

```
Environment Variables:
```

VECTORIZATION\_LEVEL=fast|balanced|best|off

```
Defaults:
```

```
VectorizationConfig {
```

```
VectorizationLevel
Quality/speed trade-off levels.
```

```
pub enum VectorizationLevel {
```

```
ExecutionProvider
Hardware acceleration backend.
```

```
pub enum ExecutionProvider {
```

```
Module Structure
```

```
Core Modules
```

- **model\_manager**: Lazy-loading model lifecycle management
- **embedder**: ONNX Runtime text embedding
- **downloader**: Model downloading and caching
- **config**: Configuration types and environment parsing

```
Dependencies
```

```
ML Dependencies (feature = "ml")
```

- **ort**: ONNX Runtime bindings for inference
- **tokenizers**: HuggingFace tokenizers for text preprocessing
- **ndarray**: N-dimensional arrays for tensor operations
- **once\_cell**: Lazy static initialization

```
Core Dependencies
```

- **tokio**: Async runtime for downloads
- **request**: HTTP client for model downloads
- **serde**: Configuration serialization
- **simd-json**: High-performance JSON

## OP-DBUS / BigPickle

```
Utilities
- **sha2**: SHA256 checksums for model verification
- **num_cpus**: CPU count detection for threading
- **anyhow/thiserror**: Error handling
- **tracing/log**: Logging
```

```
Usage
```

```
Basic Embedding
```

```
use op_ml::ModelManager;

#[tokio::main]

// Embed text (lazy loads model on first call)

println!("Embedding dimension: {}", embedding.len());

Ok()
```

```
Configuration
```

```
use op_ml::{VectorizationConfig, VectorizationLevel, ExecutionProvider};

// Create custom config

// Create manager with config
```

```
Environment-Based Configuration
```

## Set quality level

```
export VECTORIZATION_LEVEL=best
```

## Use CUDA GPU

```
export VECTORIZATION_PROVIDER=cuda
```

## Run application

```
./my-app
```

```
// Load config from environment
```

```
Batch Embedding
```

```
// Embed multiple texts efficiently

let embeddings = manager.embed_batch(&texts)?;

for (i, embedding) in embeddings.iter().enumerate() {
```

```
Semantic Similarity
```

```
// Compute cosine similarity between embeddings

// Compare documents

let sim_1_2 = cosine_similarity(&doc1, &doc2);

println!("Similarity 1-2: {:.3}", sim_1_2); // High
```

```
Model Download
```

```
use op_ml::{ModelDownloader, VectorizationLevel};
```

OP-DBUS / BigPickle

```
// Create downloader

// Ensure model is downloaded

println!("Model cached at: {:?}", model_path);
```

```
Feature Flags

`ml` Feature
The ML functionality is behind a feature flag to make it optional:
```

[dependencies]

```
Without `ml` feature:
- Minimal dependencies
- Stub implementations return empty vectors
- No ONNX Runtime dependency
- Suitable for environments without ML requirements

With `ml` feature:
- Full ML capabilities
- ONNX Runtime and tokenizers included
- Larger binary size
- Requires ONNX Runtime system libraries

Performance Considerations

Model Loading
- **First Call**: 100-500ms (model load + inference)
- **Subsequent Calls**: 1-10ms (inference only)
- **Batch Processing**: More efficient than individual calls

Memory Usage
- **Fast Model**: ~100MB RAM
- **Balanced Model**: ~150MB RAM
- **Best Model**: ~300MB RAM

Throughput
Backend	Embeddings/sec	Latency
CPU (8 threads)	100-200	5-10ms
CUDA	500-1000	1-2ms
TensorRT	1000-2000	0.5-1ms

Optimization Tips
- Use batch embedding for multiple texts
- Choose appropriate quality level for use case
- Enable GPU acceleration when available
- Reuse ModelManager instance (singleton pattern)

Integration Points

Semantic Search
```

```
// Search D-Bus interfaces by natural language

// Compare with interface descriptions

if similarity > 0.7 {
```

### Agent Routing

```
// Route user query to appropriate agent

let mut best_agent = None;

for agent in agents {

if score > best_score {
```

## Error Handling

```
Common Errors
- **Model Not Found**: Model not downloaded or cache corrupted
```

## OP-DBUS / BigPickle

```
- **ONNX Runtime Error**: Inference failure or invalid input
- **Tokenization Error**: Text encoding issues
- **GPU Not Available**: Requested GPU backend not available

Recovery Strategies
- Automatic fallback to CPU if GPU unavailable
- Model re-download on checksum mismatch
- Graceful degradation when ML disabled

Testing

Unit Tests
- Configuration parsing
- Model path resolution
- Embedding dimension validation

Integration Tests
- End-to-end embedding pipeline
- Model download and caching
- Multi-backend execution

Benchmarks
- Embedding throughput
- Batch vs individual performance
- Backend comparison

Future Enhancements

- **Vector Database Integration**: Native vector storage
- **Quantization**: INT8/FP16 models for faster inference
- **Model Fine-tuning**: Domain-specific model training
- **Multilingual Support**: Non-English embedding models
- **Streaming Embeddings**: Process large documents in chunks
- **Caching**: LRU cache for frequently embedded texts
- **Distributed Inference**: Load balancing across GPUs
- **Model Versioning**: Support multiple model versions

Related Crates

- **op-agents**: Agent routing using embeddings
- **op-introspection**: Semantic D-Bus interface search
- **op-chat**: Context-aware conversation using embeddings
- **op-plugins**: Plugin discovery by semantic matching

<file path="op-network/src/bin/op-ovsbr0-setup.rs">
 //!
 //! Replaces the original (deleted-source) Rust binary that always created the
 //! bridge with datapath_type=system. Uses the rovs crate family to manipulate
 //! OVSDb directly and the vswitchd unixctl socket to stop the daemon cleanly.
 //! No ovs-vsctl/ovsdb-client shell commands are used. `ovs-dpctl del-dp` is
 //! used only while vswitchd is down to clear stale kernel datapath state.
 //!
 //! Environment variables:
 //! BRIDGE OVS bridge name (default: ovsbr0)
 //! VETH_HOST Veth to add as port (default: grpc-uplink)
 //! FAIL_MODE OVS fail mode (default: standalone)
 //! SHARED_MAC Bridge/container MAC (default: fa:16:3e:f1:71:d2)
 //! OVSDb_SOCKET Path to OVSDb socket (default: auto-detect)
 //! VSWITCHD_SVC s6 service path (default: /run/service/ovs-vswitchd)
 //! VSWITCHD_CTL Glob for vswitchd unixctl socket
 //! (default: /usr/local/var/run/openvswitch/ovs-vswitchd.*.ctl)
 //!
 //! Modes:
 //! --seed-only Write OVSDb netdev bridge/port rows and exit. This is
 //! for the s6 ovs-vswitchd run script before vswitchd starts.

//!
//! **DEPRECATED CONTAINER PATH:** The `wg-xray` Incus container is deprecated
//! and stopped. Xray now runs on the HOST via the `gbr-xray` s6 service, so
//! the container-targeted XDP orchestration in this binary is no longer the
//! active path for xray ingress. The code is retained for historical
//! reference and potential host-side adaptation; `CT = "wg-xray"` below is
//! kept as-is because the orchestration helpers still reference it.
//!
//! TODO(host-xdp): When a clear host-side interface name for xray XDP is
//! confirmed, repoint the orchestration to drive the host path directly
//! instead of the deprecated container.
//!
//! This binary keeps the existing interface names:
//! - host uplink: `eth0`
//! - Incus host-side peer: `veth-warp`
//! - container: `wg-xray` (deprecated)
//!
//! The BPF program runs on host `eth0` and redirects matching traffic to the
//! Incus peer `veth-warp`. The Incus hook order is explicit:
//! 1. `prepare`: set the container MAC and restart the container.
//! 2. `hostside`: attach XDP after `veth-warp` exists and the container is up.
//! 3. `detach`: remove XDP before container shutdown.
//! 4. `watch`: verify the state and reapply the hostside setup if needed.

 //! D-Bus proxies for the op-openvswitch-daemon
 //!
 //! These zbus proxy types allow any crate in the workspace to call the
 //! hypervisor daemon through D-Bus instead of directly linking rovs_ovsdb
 //! or shelling out to ovs-vsctl / ovs-ofctl.
 //!
 //! Locked design (AGENTS.md §4):
 //! - Daemon paths: `org.opdbus.rovs.jsonrpc` and `org.opdbus.rovs.openflow`
 //! - Interfaces: `org.opdbus.rovs.jsonrpc` and `org.opdbus.rovs.openflow`
 //! - The daemon is a pure passthrough; business logic stays in the plugins.

Spec files analyzed: SPEC.md
Analysis mode: Current system state specification with spec-alignment notes

Summary

| Category | Count |
|---|---|
| Rust source files | 9 |
| Proto files | 0 |
| Binary targets | 0 |
| UI files | 0 |
| Root-declared modules | 8 |
| Partial artifacts | 0 |
| Spec-listed source files | 9 |
| Spec-listed but missing | 0 |
| Extra implementation files | 0 |

Current Implementation Overview

- Native networking: OpenFlow (all versions, pure Rust), OVSDB JSON-RPC, rtnetlink, Proxmox API, container networking
- Internal crate integrations: op-core.

Module / File Comparison

| Module or File | State | Current Role | Notes |
|---|---|---|---|

Feature / Capability Comparison

| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
- `op-core` - not listed in SPEC dependency block

External Runtime Dependencies
- `tokio` - documented in SPEC
- `serde` - documented in SPEC
- `simd-json` - documented in SPEC
```

```
- `anyhow` - documented in SPEC
- `thiserror` - documented in SPEC
- `tracing` - documented in SPEC
- `async-trait` - documented in SPEC
- `futures` - documented in SPEC
- `rtnetlink` - documented in SPEC
- `log` - documented in SPEC
- `request` - documented in SPEC
- `netlink-sys` - documented in SPEC
- `netlink-packet-core` - documented in SPEC
- `netlink-packet-generic` - documented in SPEC
- `netlink-packet-utils` - documented in SPEC
- `netlink-packet-route` - documented in SPEC
- `byteorder` - not listed in SPEC dependency block
- `libc` - not listed in SPEC dependency block

Development and Build Dependencies
- None

Notes and Observations

- Local documentation files present: SPEC.md.
- Root module declarations found in `lib.rs`/`main.rs`: openflow, ovs_capabilities, ovs_error, ovs_netlink, ovssdb, plugin, proxmox
- 3 runtime dependencies are present in `Cargo.toml` but omitted from the SPEC dependency block.
</file>

 //! (`op-blockchain`) through the `org.opdbus.v1.plugins` surface, reachable over
 //! `PluginService.CallMethod`.
 //!
 //! This is the correct home for the capability the Lovable frontend mistakenly
 //! called as a standalone `operation.blockchain.v1.BlockchainService` gRPC
 //! capabilities register here as plugins; the served gRPC surface stays the one
 //! shared route-builder.
 //!
 //! Every read is live: the plugin's live state
 //! opens the on-disk chain at `$OPDBUS_BLOCKCHAIN_PATH` and reports its real
 //! snapshots, DR `current_state`, snapshot interval and retention policy.
 //! [`create_checkpoint`](BlockchainPlugin::create_checkpoint) performs a real
 //! `create_snapshot()` and `apply_state` writes the DR state through the chain.
 //! Nothing here is mocked.

 /*! (`op-state-store`) through the `org.opdbus.v1.plugins` surface (PluginService).
 /*!
 /*! This is the correct home for the capability the Lovable frontend mistakenly
 /*! there is no such proto and there must not be one (see OD-30).
 /*!
 /*! The read is **live, not mocked**: the plugin's live state calls
 /*! `StateStore::export_canonical()` on the *same shared store handle* the rest
 /*! of the process uses (injected at registration via `PluginCtx::state_store`),
 /*! so there is no second DB open / lock contention. It reports the real object
 /*! index (id/type/namespace), per-namespace counts and execution/blockchain row
 /*! counts.
 /*!
 /*! The store is mutable, but writes flow through the MutationEngine and the
 /*! owning plugins (every mutation is an enforcement point). This projection is
 /*! therefore read-only: it rejects state-diff mutations with an explanation
 /*! rather than letting arbitrary objects be upserted around the enforcement path.

 //! Generic, provider-agnostic embedding-model plugin.
 //!
 //! output dimensionality. The model is a FIELD, not the plugin's identity: swap
 //! `model_id`. This is the ONLY plugin that knows how to reach an embedding
 //! provider; consumers (ctl_plane_chatbot, knowledge, memory, notebooklm)
 //! delegate here and embed no model of their own. It is the embedding sibling of
 //! [`super::large_language_model`].
 //!
 //! Embeddings are a different KIND from generation: the method surface is
 //! the voyage-4 trio writes one 1024-dim Qdrant collection with no re-index on
 //! model switch.
 //!
 //! The plugin reports the *live* observed state. Providers differ: Ollama serves
 //! embeddings and enumerates models (`GET {endpoint}/api/tags`), so the active
 //! model can be resolved by lookup; Voyage is a cloud API (`POST /v1/embeddings`)
 //! with no model-list endpoint, so it is reachable iff an API key is present and
 //! the active model is config-driven. Either way, no active model is hardcoded.

<file path="op-plugins/src/state_plugins/freedesktop.rs">
 //! FreeDesktop Plugin
 //!
 //! Implements FreeDesktop D-Bus standards support including:
 //! - org.freedesktop.DBus.ObjectManager
 //! - org.freedesktop.DBus.Properties
 //! - org.freedesktop.DBus.Introspectable
 //! - org.freedesktop.DBus.Peer
 //!

```

## OP-DBUS / BigPickle

```
//! This plugin follows the canonical path convention:
//! - D-Bus Path: /org/opdbus/v1/plugins/freedesktop
//! - Interface: org.opdbus.v1.Plugin.Plugins.FreeDesktop
//! - Schema: schemas/plugin/freedesktop.json
//!
//! ## Architecture
//!
//! The FreeDesktop plugin provides a schema-backed implementation of standard
//! FreeDesktop D-Bus interfaces. It acts as a reference implementation for how
//! plugins should be structured in this system.
//!
//! ## Canonical Path Compliance
//!
//! This plugin uses the canonical paths as defined in `crate::canonical`:
//! - Object path prefix: `/org/opdbus/v1/plugins/`
//! - Interface prefix: `org.opdbus.v1.Plugin.Plugins`
//!
//! Legacy paths like `/opdbus/v1/plugins/` or `/org/opdbus/v1/plugin/plugins/`
//! are normalized to the canonical prefix by `crate::canonical::normalize_plugin_path`.

 //! Full System State Plugin
 //!
 //! This plugin captures the COMPLETE system state for disaster recovery.
 //! It aggregates state from all other plugins into a single JSON document
 //! that can be used to reinstall/restore the entire system.
 //!
 //! ## State Categories
 //!
 //! - **system**: hostname, timezone, locale, kernel parameters
 //! - **network**: interfaces, routes, DNS, bridges, VLANs
 //! - **services**: systemd units and their configurations
 //! - **packages**: installed packages and versions
 //! - **users**: user accounts and groups
 //! - **storage**: mounts, fstab entries
 //! - **containers**: LXC/Docker containers
 //! - **security**: firewall rules, SELinux/AppArmor policies
 //!
 //! This plugin is special: it queries OTHER plugins to build the full state.

<file path="op-plugins/src/state_plugins/incus_device.rs">
 //! Typed model of Incus instance **devices**, faithful to the official Incus
 //! API (`shared/api`: `map[string]map[string]string`).
 //!
 //! Incus stores every device value as a string (`"nat": "true"`, `"uid": "0"`).
 //! To present a typed, schema-renderable model while round-tripping losslessly
 //! with the REST API, numeric/boolean keys use the [`StrBool`]/[`StrInt`]
 //! coercion newtypes: they deserialize from either a JSON string or a native
 //! value and **always serialize back to a string**, so a `Device` round-trips
 //! to the all-string map Incus expects.
 //!
 //! [`Device`] is an internally-tagged enum (`#[serde(tag = "type")]`) with one
 //! variant per device type. Through [`super::schemars_adapter`] it renders into
 //! the plugin schema as a `FieldType::OneOf` discriminated union (the `oneOf`
 //! emitted by schemars for the tagged enum). The device *name* (the Incus map
 //! key) is carried alongside in [`NamedDevice`] so the `devices` field renders

 //! Generic, model-agnostic large-language-model plugin.
 //!
 //! `llama3`/`mistral` by changing `model_id`. This is the ONLY plugin that knows
 //! about Ollama; consumers (e.g. UI-gen / agents) talk to this surface and embed
 //! no model of their own.
 //!
 //! The plugin reports the *live* observed state: it queries the
 //! provider (`GET {endpoint}/api/tags` for Ollama) for the available models and
 //! reachability. The schema is published to the SHM folder/manifest by
 //! op-projection's enumerator; this plugin does not self-write `/dev/shm`.

<file path="op-plugins/src/state\_plugins/plugin-struct.txt">

Ran 2 shell commands (ctrl+o to expand)

check the service state.

Ran 2 shell commands (ctrl+o to expand)

what the service actually launches.

Read 1 file, ran 1 shell command (ctrl+o to expand)

status and double-check no binary is running.

Ran 1 shell command (ctrl+o to expand)

boot.

- Process: Only the s6-supervise op-cognitive-mcp watchdog (PID 12151) is alive; no /usr/local/bin/op-cognitive-mcp binary process exists.
- Port: Nothing listening on 50052 (the tonic-web gRPC transport external MCP clients use).

The supervisor is up but the binary is down. Want me to start it? That'd be:

```
sudo s6-svc -u /run/s6-rc/servicedirs/op-cognitive-mcp
```

(or via the s6 CLI). Say the word and I'll bring it up and re-verify the port is listening.

Ran 2 shell commands (ctrl+o to expand)

Let me find and remove it to make it persistent.

Ran 1 shell command (ctrl+o to expand)

or repo. I need to understand the s6-rc compile workflow to make removal persistent across reboots. Let me check the recompile script and the compiled database.

Read 1 file, ran 1 shell command (ctrl+o to expand)

database used at boot doesn't carry a down flag (my last find didn't follow the symlink into /etc/s6/rc). Let me check the actual compiled db and the canonical repository.

Ran 1 shell command (ctrl+o to expand)

so boot persistence is already correct. The down file in the live servicedir is stale runtime state (someone ran s6-svc -d manually). Let me remove it so the running state is consistent, and confirm the service is in the default boot bundle.

Ran 1 shell command (ctrl+o to expand)

contents. Let me verify it's actually reachable from the default boot bundle

(it may be pulled in transitively).

Ran 1 shell command (ctrl+o to expand)

uses the s6 frontend CLI (per the canonical recompile-and-update.sh). Let me learn the proper s6 interface for bundle membership.

Listed 1 directory, ran 2 shell commands (ctrl+o to expand)

bundle because it's not enabled in the working set. Let me check its current enable state.

Ran 1 shell command (ctrl+o to expand)

that's why it's absent from the default boot bundle. Enabled services show /active (like gemma, wg-chatbot). Let me enable it (dry-run first to check dependency implications).

Ran 1 shell command (ctrl+o to expand)

and verify the working-set status flips to active.

Ran 1 shell command (ctrl+o to expand)

canonical recompile-and-update.sh (the Artix-safe path that preserves the default boot bundle).

Ran 1 shell command (ctrl+o to expand)

bundle tree and still running.

Ran 1 shell command (ctrl+o to expand)

down again. Let me start it the proper s6 way via the s6 live frontend.

Ran 3 shell commands (ctrl+o to expand)

throughout.

What was wrong

- Service was down (not started yet) with a stale manual down flag.
- Root cause of non-persistence: it was op-cognitive-mcp/usable in the working bundle and would never auto-start.

Fix (Artix s6 frontend, not raw s6-svc)

the default boot bundle

Verified

- Listening: 10.220.35.1:50052 (tonic-web gRPC, the external MCP client)

It will now start automatically on boot and be restarted by its supervisor if it crashes.

Let me record the enable workflow, since it refines the existing Artix s6 memory.

Recalled 1 memory, wrote 1 memory (ctrl+o to expand)

workflow (no new index entry needed since it already exists in MEMORY.md).

Summary: cognitive-mcp is up (pid 4064) on 10.220.35.1:50052, enabled in the default boot bundle, and will auto-start on boot + auto-restart on crash.

endpoint. Let me probe it via reflection and tool discovery.

Searched for 2 patterns (ctrl+o to expand)

Let me discover the gRPC services via reflection and read the example to understand what "context aware coding" exercises.

Ran 2 shell commands (ctrl+o to expand)

methods and find the context-aware coding tools.

Searched for 1 pattern, ran 1 shell command (ctrl+o to expand)

server's health and trace how those tools are exposed for invocation.

Searched for 1 pattern, ran 1 shell command (ctrl+o to expand)

my anonymous localhost call was rejected with Unauthenticated: Missing Ghostbridge Identity Sled. That's the xraqy/WG identity gate doing its job. To genuinely test context-aware coding I need to present the Ghostbridge identity the way a real client does. Let me find how that identity is supplied.

Searched for 1 pattern, read 1 file (ctrl+o to expand)

traffic: x-ghostbridge-footprint and x-ghostbridge-trace-id. From localhost injection to test end-to-end. But first, the coding tools live on the MCP

Read 1 file (ctrl+o to expand)

code\_search/code\_context/code\_index live via RegistryExecutor). Let me see which ports the running process actually listens on and how main.rs wires them.

Ran 1 shell command (ctrl+o to expand)

coding tools are) and gRPC on 50052. Let me find the MCP HTTP route paths so I can drive a real tools/list + code\_search.
