//! Intent-Based Tool Executor
//!
//! This module provides a DETERMINISTIC execution layer that:
//! 1. Parses user intent from natural language
//! 2. Maps intents to registered tools
//! 3. Executes tools DIRECTLY (not via LLM)
//! 4. Returns verified results
//!
//! This bypasses LLM tool-calling limitations (like HuggingFace)
//! and ensures tools are ACTUALLY executed, not hallucinated.

///! Natural Language Server Administration
///!
///! This is the CORE module that enables natural language server administration.
///! It coordinates between:
///! - LLM (understands user intent)
///! - Tool Registry (executes operations)
///! - Response formatting (user-friendly output)
///!
///! The key insight: We instruct the LLM via system prompt to ALWAYS use tools,
///! then parse and execute those tool calls.

// =====
// FIXED PART - DO NOT ALLOW EDITING
// =====

/// Base system prompt with anti-hallucination rules (FIXED - NOT EDITABLE)

Capabilities:
- **Container orchestration** via Incus (`assistant`, `mail-3tched`)
- **Network configuration** via rtnetlink and Generic Netlink
- **D-Bus** system bus for inter-process communication
- **Graph queries** via CozoDB over the full object and service tree

YOU MUST USE TOOLS FOR EVERYTHING - INCLUDING RESPONDING TO THE USER.

This system uses a "forced tool execution" architecture. There are two types of tools:

1. Action Tools (for doing things)
- `ovs_create_bridge`, `ovs_delete_bridge`, `ovs_add_port`
- `s6_*` tools for service management
- `incus_*` tools for container management
- Any tool that changes system state

2. Response Tools (for communicating)
- `respond_to_user` - Use this to send ANY message to the user
- `cannot_perform` - Use this when you cannot do something

WORKFLOW:
1. User asks you to do something
2. Call the appropriate ACTION TOOL
3. Then call `respond_to_user` to explain the result

EXAMPLES:

User: "Create an OVS bridge called ovsbr0"
You should call:
1. `ovs_create_bridge {"name": "ovsbr0"}` - Actually creates the bridge
2. `respond_to_user {"message": "Created OVS bridge ovsbr0", "message_type": "success"}`

User: "What bridges exist?"
You should call:
1. `ovs_list_bridges {}` - Gets the list
2. `respond_to_user {"message": "Found bridges: ovsbr0", "message_type": "info"}`

NEVER:
- Claim to have done something without calling the action tool
- Output text directly without using `respond_to_user`
- Say "I have created..." when you haven't called the action tool

OVS Tools

Available (registered):
- `ovs_list_bridges {}` - List all OVS bridges
- `ovs_list_ports {"bridge": "ovsbr0"}` - List ports on a bridge
- `ovs_show_bridge {"bridge": "ovsbr0"}` - Show bridge detail
- `ovs_dump_flows {"bridge": "ovsbr0"}` - Dump OpenFlow flows

Network interfaces (native rtnetlink):
- `list_network_interfaces {}` - List all interfaces with addresses, state, MTU

OVS write operations:
Write tools (add/delete bridge, add/delete port) are not yet registered. For bridge/port mutations use `shell_execute` to invoke `

s6 Service Management

THIS HOST USES s6, NOT systemd. `systemctl` is FORBIDDEN.

Adding a new service (exact pattern)
```

OP-DBUS / BigPickle

All service source files live in `deploy/s6/` (git-tracked), then copied to `/etc/s6/sv/`.

**srv service** (`deploy/s6/op-<name>-srv/`):

dependencies.d/

**log service** (`deploy/s6/op-<name>-log/`):

**Logger run template** (execlineb):

#!/bin/execlineb -P

**Deploy sequence:**

sudo cp -r deploy/s6/op-<name>-srv /etc/s6/sv/

**DO NOT use:**

**CRITICAL: NEVER use or suggest these CLI tools:**

### CORRECT Approach:

Instead of...	Use...	
-----	-----	
`ovs-vsctl add-br ovsbr0`	`ovs_create_bridge {"name": "ovsbr0"}`	
`ovs-vsctl list-br`	`ovs_list_bridges {}`	
`ovsdb-client ...`	rovs-ovsdb Client + Transaction	
`ovs-ofctl add-flow ...`	rovs-openflow Flow builder	
`systemctl restart X`	`s6-rc -v2 -u change <name>` or s6 tools	
`ip addr show`	`list_network_interfaces {}`	
`incus exec ...`	`incus_exec {"container": "...", ...}`	

## File Operations

- `read\_file {"path": "/etc/hosts"}` - Read file contents
- Use PluginSchema projection tools (`plugin\_projection\_\*`) or native D-Bus/rtnetlink tools for system state

## Rules

1. **ALWAYS** use `respond\_to\_user` for all communication
  2. **ALWAYS** call action tools BEFORE claiming success
  3. **NEVER** suggest CLI commands
  4. **NEVER** say "run this command:" followed by shell commands
  6. Use native protocol tools (rovs suite, D-Bus, rtnetlink, s6) exclusively
  7. Report actual tool results, not imagined outcomes
- "#;

/// Network topology specification (FIXED - NOT EDITABLE)  
const FIXED\_TOPOLOGY\_SPEC: &str = r#"  
## CURRENT NETWORK TOPOLOGY

### Host

OS: Artix Linux (xanmod kernel), s6 service supervision

### Interfaces

INTERFACE	ADDRESS	TYPE	PURPOSE
-----------	---------	------	---------

BRIDGE	DATAPATH	FAIL_MODE	DESCRIPTION
--------	----------	-----------	-------------

- veth port: `grpc-uplink` (host op-dbus operation.v1 gRPC at 10.200.0.2:50051)

### Port Naming Convention

PREFIX	VLAN	SUBNET	PURPOSE
--------	------	--------	---------

### Incus Containers

NAME	STATE	IP	PURPOSE
------	-------	----	---------

now run on the host (xray via the `gbr-xray` s6 service; operation.v1 gRPC at

```
`10.200.0.2:50051` served by `op-dbus`).
```

```
Traffic Flow
```

```
Socket Paths
```

SERVICE	SOCKET PATH	PROTOCOL
---------	-------------	----------

```
s6 Services
```

SERVICE	PURPOSE
---------	---------

```
Expected State
When properly configured:
- ovsbr0 UP with datapath=netdev, grpc-uplink as veth port
- eth0 AF_XDP program attached (id 54), management IP on ovsbr0 internal port when bridge is up
- netmaker UP, 100.90.37.254/32, WireGuard mesh active
- Xray + gRPC-bridge running on the HOST (gbr-xray s6 service; operation.v1
 gRPC at 10.200.0.2:50051 served by op-dbus); the wg-xray container is stopped

//! Tool Loader - Registers all tools with the ToolRegistry
//!
//! This module loads and registers 200+ tools from various sources:
//! - Builtin tools (filesystem, response, shell) - ALWAYS LOADED
//! - D-Bus discovered tools (systemd, NetworkManager, etc.) - LAZY LOADED
//! - Plugin state tools (query, diff, apply) - LAZY LOADED
//! - Agent tools (from op-agents) - LAZY LOADED
//! - OVS tools (bridge, port, flow management) - LAZY LOADED
//!
//! Uses context-aware lazy loading via ToolFactory pattern:
//! - Critical tools are pre-loaded immediately
//! - Domain-specific tools are loaded on-demand via factories
//! - LRU caching automatically evicts unused tools

Spec files analyzed: SPEC.md, DESIGN.md
Analysis mode: Current system state specification with spec-alignment notes

Summary

| Category | Count |
|---|---|
| Rust source files | 33 |
| Proto files | 2 |
| Binary targets | 1 |
| UI files | 0 |
| Root-declared modules | 10 |
| Partial artifacts | 2 |
| Spec-listed source files | 16 |
| Spec-listed but missing | 2 |
| Extra implementation files | 19 |

Current Implementation Overview

- Chat functionality and LLM integration for op-dbus-v2
- Internal crate integrations: op-core, op-tools, op-introspection, op-llm, op-execution-tracker, op-agents, op-mcp, op-grpc-bridg
- Protocol assets: 2 `proto` files.

Module / File Comparison

- `tokio-stream` - not listed in SPEC dependency block
- `prost` - not listed in SPEC dependency block
- `prost-types` - not listed in SPEC dependency block
- `tracing-subscriber` - not listed in SPEC dependency block

Development and Build Dependencies
- `dev:tokio-test`
- `build:tonic-build`
- `build:prost-build`

Notes and Observations

- Local documentation files present: DESIGN.md, SPEC.md, src/orchestration/skills_builtin/architecture_patterns.md, src/orchestrat
- Transitional or partial artifacts detected: src/tool_loader.rs.copied, src/tool_loader.rs.stub.
- Spec/design docs reference source files that are not present in the current tree: src/builtin/response_tools.rs, src/orchestrati
- Current implementation contains 19 Rust source files beyond the explicit spec/design source inventory.
- Root module declarations found in `lib.rs`/`main.rs`: actor, agent_tools, forced_execution, forced_tool_pipeline, mcp_server, nl
- RPC or protocol definition files: proto/agents.proto, proto/orchestration.proto.
</file>

op-chat Design Document

Project: op-chat - Chat Orchestration Layer for op-dbus-v2
Status: Design Phase
Version: 1.0
Date: 2026-02-16
Authors: op-dbus-v2 team

Executive Summary

`op-chat` is the intelligent orchestration layer that transforms natural language into verified system operations. It serves a

Core Innovation
```

## OP-DBUS / BigPickle

```
Zero-Trust LLM Architecture: Unlike traditional chatbots that trust LLM output, op-chat enforces a "forced tool execution" mod
- LLMs cannot output text directly to users
- All actions must go through verified tool calls
- Claims are validated against execution logs
- Hallucinations are detected and blocked

This architecture makes it **impossible** for the LLM to hallucinate system changes.

Key Capabilities

2. **Multi-Agent Orchestration**: Coordinate specialized agents (rust_pro, memory, sequential_thinking)
3. **Complex Workflows**: Multi-phase workstacks with rollback support
4. **Full Auditability**: Every action tracked with who/what/when/result
5. **MCP Server**: Expose capabilities via Model Context Protocol

Table of Contents

14. [Deployment Architecture](#14-deployment-architecture)
15. [Future Roadmap](#15-future-roadmap)

1. Vision & Goals

1.1 Vision Statement

Enable **safe, natural language server administration** where users can express intent in plain English and have the system execut

1.2 Primary Goals

1. **Safety First**: Prevent LLM hallucinations from causing system changes
2. **Natural Interface**: Users shouldn't need to know CLI syntax or API details
3. **Full Auditability**: Every action logged with complete context
4. **Extensibility**: Easy to add new tools, agents, and workflows
5. **Performance**: Sub-second response for simple operations, streaming for complex ones

1.3 Non-Goals

- **Not a general chatbot**: Focused on system administration, not conversation
- **Not autonomous**: Requires user intent, doesn't make decisions independently
- **Not a replacement for experts**: Augments expertise, doesn't replace it

1.4 Success Metrics

- **Hallucination Rate**: < 0.1% (1 in 1000 operations)
- **Intent Recognition**: > 95% accuracy for common operations
- **Response Time**: < 1s for simple operations, < 5s for complex
- **Uptime**: 99.9% availability
- **Audit Coverage**: 100% of operations tracked

2. Requirements

2.1 Functional Requirements

FR1: Natural Language Processing
- **FR1.1**: Accept natural language input in English
- **FR1.2**: Parse user intent and map to tool operations
```

## OP-DBUS / BigPickle

```
- **FR1.3**: Handle ambiguous requests with clarification
- **FR1.4**: Support multi-step operations in single request

FR2: Tool Execution
- **FR2.1**: Execute tools from registry with argument validation
- **FR2.2**: Track all executions with full context
- **FR2.3**: Rate limit per session (60/min, 500/hour)
- **FR2.4**: Support synchronous and streaming execution

FR3: Anti-Hallucination
- **FR3.1**: Force all LLM output through response tools
- **FR3.2**: Verify claimed actions against execution log
- **FR3.3**: Detect and block 5 hallucination types
- **FR3.4**: Provide detailed hallucination reports

FR4: Agent Orchestration
- **FR4.1**: Manage persistent gRPC connections to agents
- **FR4.2**: Start/stop run-on-connection agents per session
- **FR4.3**: Health check agents every 30 seconds
- **FR4.4**: Automatic reconnection with exponential backoff

FR5: Workstack Execution
- **FR5.1**: Execute multi-phase workflows with dependencies
- **FR5.2**: Support rollback on failure
- **FR5.3**: Variable substitution in tool arguments
- **FR5.4**: Progress tracking and streaming updates

FR6: Session Management
- **FR6.1**: Create and manage chat sessions
- **FR6.2**: Store conversation history
- **FR6.3**: Support WireGuard authentication
- **FR6.4**: Distinguish controller vs regular users

FR7: MCP Server
- **FR7.1**: Expose tools via MCP protocol
- **FR7.2**: Provide prompts (workstacks) and resources (skills)
- **FR7.3**: Support gRPC transport
- **FR7.4**: Handle streaming responses

2.2 Non-Functional Requirements

NFR1: Performance
- **NFR1.1**: Handle 100 concurrent sessions
- **NFR1.2**: < 1s latency for simple operations
- **NFR1.3**: < 100ms overhead for tool execution tracking
- **NFR1.4**: Support 1000+ tools in registry

NFR2: Reliability
- **NFR2.1**: 99.9% uptime
- **NFR2.2**: Graceful degradation when agents unavailable
- **NFR2.3**: Circuit breaker for failing agents
- **NFR2.4**: No data loss on crash (persistent sessions)

NFR3: Security
- **NFR3.1**: All operations authenticated
- **NFR3.2**: Role-based access control (controller vs user)
- **NFR3.3**: Complete audit trail
- **NFR3.4**: Input validation on all tool arguments

NFR4: Maintainability
- **NFR4.1**: Modular architecture with clear boundaries
- **NFR4.2**: Comprehensive logging and tracing
- **NFR4.3**: Self-documenting code with examples
- **NFR4.4**: < 10% code duplication

NFR5: Scalability
- **NFR5.1**: Horizontal scaling via multiple instances
- **NFR5.2**: Stateless design (sessions in external store)
- **NFR5.3**: Connection pooling for agents
- **NFR5.4**: Efficient resource usage (< 100MB per instance)

2.3 Constraints

Technical Constraints
```

- **TC1**: Must use Rust 2021 edition
- **TC2**: Must use gRPC for agent communication
- **TC3**: Must use SIMD JSON for performance
- **TC4**: Must integrate with existing op-tools registry
- **TC5**: Must support D-Bus native protocols

#### Business Constraints

- **BC1**: Open source (workspace license)
- **BC2**: No external API dependencies (self-contained)
- **BC3**: Must work offline (no cloud services)

#### Operational Constraints

- **OC1**: Must run on Linux (systemd/dinit)
- **OC2**: Must support x86\_64 and aarch64
- **OC3**: Must integrate with WireGuard gateway

---

### 3. Architecture Overview

#### 3.1 High-Level Architecture

#### 3.2 Design Principles

##### Principle 1: Actor Model for Concurrency

- Single-threaded message processing (no locks)
- Message passing via channels
- Clear ownership and lifecycle

##### Principle 2: Zero-Trust LLM Output

- Never trust LLM claims
- Always verify against execution log
- Force structured output (tools only)

##### Principle 3: gRPC-First Communication

- Binary protocol for performance
- Streaming for long operations
- Type-safe with protobuf

##### Principle 4: Fail-Safe Defaults

- Rate limiting enabled by default
- Tracking enabled by default
- Rollback on failure by default

##### Principle 5: Observable by Design

- Structured logging (tracing)
- Metrics at every layer
- Complete audit trail

#### 3.3 Technology Stack

##### Core Runtime

- **Language**: Rust 2021
- **Async Runtime**: Tokio (full features)
- **Serialization**: simd-json (performance)
- **Error Handling**: anyhow + thiserror

##### Communication

- **RPC Framework**: Tonic (gRPC)
- **Protocol**: Protocol Buffers 3
- **Streaming**: tokio-stream
- **D-Bus**: zbus

##### Data Management

- **Sessions**: In-memory (RwLock<HashMap>)
- **Audit Log**: op-execution-tracker
- **Metrics**: Atomic counters + aggregation

##### Observability

- **Logging**: tracing + tracing-subscriber
- **Metrics**: Custom (atomic counters)
- **Health**: gRPC health checks

```

4. Core Components

4.1 ChatActor - Central Message Bus

Responsibility
Single point of coordination for all requests. Routes messages to appropriate handlers and aggregates responses.

Design Pattern
Actor model with message passing:
```

```
pub struct ChatActor {

struct ActorMessage {
```

```
Message Flow
```

```
Key Decisions
- **Why Actor Model?**: Eliminates lock contention, clear ownership
- **Why mpsc?**: Multiple producers (clients), single consumer (actor)
- **Why oneshot?**: Each request gets exactly one response

Interface
```

```
pub enum RpcRequest {

pub struct RpcResponse {
```

```
4.2 SessionManager - Conversation State
```

```
Responsibility
Manage chat sessions with message history and authentication context.

Design
```

```
pub struct SessionManager {

pub struct ChatSession {

// Authentication
```

```
Key Decisions
- **Why in-memory?**: Fast access, simple implementation (Phase 1)
- **Why RwLock?**: Many reads (get session), few writes (add message)
- **Future?**: Persistent storage (Redis/PostgreSQL) for Phase 2

Operations
- `create_session()` - Generate UUID, initialize
- `get_session(id)` - Retrieve by ID
- `add_message(id, message)` - Append to history
- `authenticated(...)` - Create with WireGuard context
```

```
4.3 SystemPromptGenerator - LLM Context
```

```
Responsibility
Generate comprehensive system prompts with anti-hallucination rules and tool definitions.

Structure
```

SYSTEM PROMPT = FIXED\_PART + CUSTOM\_PART + TOOL\_DEFINITIONS

FIXED\_PART (immutable):

CUSTOM\_PART (mutable):

TOOL\_DEFINITIONS:

```
Key Decisions
- **Why split fixed/custom?**: Safety (fixed) + flexibility (custom)
- **Why file-based custom?**: Easy admin editing without code changes
- **Why include tools?**: LLM needs to know what's available

```

```
5. Anti-Hallucination System

5.1 Problem Statement

LLMs hallucinate. They will confidently claim to have performed actions they never executed:
- "I have created the bridge br0" (but didn't call the tool)
- "The service is now running" (but didn't start it)
- "I've updated the configuration" (but didn't write the file)

This is **unacceptable** for system administration. A hallucinated claim could lead operators to believe a system is configured wh

5.2 Solution: Forced Tool Execution Architecture

Core Concept
The LLM cannot output text directly to the user. All communication must go through verified tools.

Architecture

5.3 Component Design

ForcedExecutionOrchestrator

pub struct ForcedExecutionOrchestrator {
impl ForcedExecutionOrchestrator {

// Execute tools and verify against hallucination
// Verify response after execution

HallucinationCheck

pub struct HallucinationCheck {
pub enum HallucinationType {
pub enum IssueSeverity {

5.4 Response Tools

Special tools that LLM MUST use to communicate:

respond_to_user

{

cannot_perform

{

5.5 Verification Rules

Rule 1: No Raw Text Output

// Check if LLM output contains "content" field with text

Rule 2: Action Verification

// Check if respond_to_user claims actions that weren't executed

Rule 3: Response Tool Required

// Every turn must call respond_to_user or cannot_perform
if !has_response_tool {

Rule 4: Success Verification

// If tool failed, cannot claim success

5.6 System Prompt Rules

The system prompt enforces this architecture:
```

**\*\*YOU MUST USE TOOLS FOR EVERYTHING - INCLUDING RESPONDING TO THE USER.\*\***

WORKFLOW:

NEVER:

- \* Output text directly without using respond\_to\_user
- \* Say "I have created..." when you haven't called the tool

EXAMPLES:

User: "Create an OVS bridge called br0"

User: "What bridges exist?"

```
5.7 Implementation Phases

Phase 1: Basic Detection
- Detect raw text output
- Detect missing response tool
- Block critical hallucinations

Phase 2: Advanced Verification
- Verify related_actions claims
- Check success/failure consistency
- Detailed issue reporting

Phase 3: Learning System
- Track hallucination patterns
- Adjust system prompt based on patterns
- Provide feedback to LLM provider

6. Agent Orchestration

6.1 Problem Statement

Complex operations require specialized capabilities:
- **Rust operations**: cargo build, test, clippy
- **Memory**: Key-value storage across turns
- **Sequential thinking**: Multi-step reasoning chains
- **Architecture**: Design analysis and suggestions
- **Context**: Persistent context across sessions

We need a way to coordinate these specialized agents efficiently.

6.2 Solution: gRPC Agent Pool

Design Goals
1. **Persistent Connections**: Avoid connection overhead
2. **Health Monitoring**: Detect and handle failures
3. **Circuit Breaker**: Prevent cascading failures
4. **Streaming Support**: Long-running operations
5. **Parallel Execution**: Batch operations

Architecture

6.3 Component Design

GrpcAgentPool

pub struct GrpcAgentPool {

pub struct AgentPoolConfig {

AgentConnection

struct AgentConnection {

pub enum AgentStatus {

pub enum CircuitState {
```

\* Claim

## OP-DBUS / BigPickle

```
6.4 Circuit Breaker Pattern
```

```
State Machine
```

```
failures >= threshold
```

```
Implementation
```

```
async fn execute_with_circuit_breaker(
```

```
match conn.circuit_state {
```

```
match operation.await {
```

```
6.5 Run-on-Connection Agents
```

Agents that start automatically when a session begins:

```
pub const DEFAULT_RUN_ON_CONNECTION: &[&str] = &[
```

```
Session Lifecycle
```

```
2. GrpcAgentPool.start_session(session_id)
```

```
6.6 Operations
```

```
Execute (Single)
```

```
pub async fn execute(
```

```
Execute Stream (Long-running)
```

```
pub async fn execute_stream(
```

```
Batch Execute (Parallel)
```

```
pub async fn batch_execute(
```

```
6.7 Health Checking
```

Background task that runs every 30 seconds:

```
async fn health_check_loop(pool: Arc<GrpcAgentPool>) {
```

```
loop {
```

```
let connections = pool.connections.read().await;
```

```

```

```
7. Workstack System
```

```
7.1 Problem Statement
```

Complex operations require multiple steps with dependencies:

- **Rust project setup**: Create project, add dependencies, configure CI, write tests
- **Microservice deployment**: Build, test, containerize, deploy, configure monitoring
- **Database migration**: Backup, validate, migrate, verify, rollback if needed

We need a way to define and execute these multi-phase workflows reliably.

```
7.2 Solution: Workstacks
```

```
Concept
```

A **workstack** is a multi-phase workflow with:

- **Phases**: Ordered steps with dependencies
- **Tools**: Operations to execute in each phase
- **Variables**: Shared state across phases
- **Rollback**: Undo operations on failure
- **Conditions**: Skip phases based on state

```
Example: Rust Project Setup
```

```
id: rust_project_setup
```

OP-DBUS / BigPickle

phases:

- id: add\_dependencies
- id: configure\_ci
- id: write\_tests
- id: verify

```
7.3 Component Design

Workstack
```

```
pub struct Workstack {

WorkstackPhase

pub struct WorkstackPhase {

pub enum PhaseStatus {

PhaseToolCall

pub struct PhaseToolCall {
```

```
7.4 WorkstackExecutor
```

```
pub struct WorkstackExecutor {

impl WorkstackExecutor {

async fn execute_phase(

async fn rollback_phase(

fn resolve_dependencies(
```

```
7.5 Execution Flow
```

1. Validate Workstack
2. Resolve Dependencies
3. Initialize Variables
4. Execute Phases (in dependency order)
5. Return WorkstackResult

```
7.6 Variable Substitution

Variables can be referenced in tool arguments:

{
```

```
Implementation:
```

```
fn substitute_variables(
```

```
7.7 Built-in Workstacks

Phase 1 (MVP)
1. **rust_project_setup** - Initialize Rust project
2. **microservice_deployment** - Deploy microservice
3. **database_migration** - Safe DB migration

Phase 2
4. **security_audit** - Security analysis
5. **performance_optimization** - Profile and optimize
6. **disaster_recovery** - Backup and recovery
7. **ci_cd_pipeline** - CI/CD setup
8. **monitoring_setup** - Prometheus + Grafana
```

## OP-DBUS / BigPickle

```
9. **load_testing** - Performance testing
10. **code_review** - Automated review
```

```

```

```
8. Protocol Design
```

```
8.1 gRPC Service Definitions
```

We need two protocol layers:

1. **\*\*Orchestration Protocol\*\***: Full-featured for external clients
2. **\*\*Internal Agent Protocol\*\***: Simplified for chatbot-to-agent communication

```
8.2 Orchestration Protocol (orchestration.proto)
```

```
AgentLifecycle Service
```

```
service AgentLifecycle {
```

```
Design Decisions:
```

- ``StartSession``: Idempotent, returns already-started agents
- ``WatchAgents``: Server streaming for real-time status updates
- ``Shutdown``: Graceful shutdown with timeout

```
AgentExecution Service
```

```
service AgentExecution {
```

```
Design Decisions:
```

- ``Execute``: Synchronous, waits for completion
- ``ExecuteStream``: Server streaming for long operations (cargo build, tests)
- ``BatchExecute``: Parallel or sequential execution of multiple operations
- ``Cancel``: Best-effort cancellation with correlation ID

```
MemoryService
```

```
service MemoryService {
```

```
Design Decisions:
```

- Simple key-value operations for high frequency
- Bulk operations use streaming for efficiency
- TTL support for automatic expiry
- Tags for categorization and filtering

```
SequentialThinkingService
```

```
service SequentialThinkingService {
```

```
Design Decisions:
```

- Chain-based reasoning with max steps
- Streaming for real-time thinking process
- Fork support for exploring alternatives
- Confidence scoring per thought

```
RustProService
```

```
service RustProService {
```

```
Design Decisions:
```

- Quick operations (check, fmt) are synchronous
- Long operations (build, test) stream output
- Separate stdout/stderr/compiler streams
- Analysis for dependencies, structure, complexity

```
WorkstackService
```

```
service WorkstackService {
```

```
Design Decisions:
```

- Execute streams events for progress tracking
- Status query for monitoring
- Cancel with optional rollback
- Partial rollback (to specific phase)

```
8.3 Internal Agent Protocol (agents.proto)
```

Simplified protocol for chatbot-to-agent communication:

```
service AgentService {
```

```
 Design Decisions:
 - Unified `Execute` operation (agent determines what to do)
 - Bidirectional `Session` stream for entire session lifecycle
 - Simpler than orchestration protocol (fewer services)
```

```
 ### 8.4 Message Design Patterns
```

```
 #### Request/Response Pattern
```

```
message ExecuteRequest {
```

```
message ExecuteResponse {
```

```
 Design Decisions:
 - JSON payloads for flexibility (avoid proto changes)
 - Correlation ID for request tracking
 - Execution time for metrics
 - Metadata for extensibility
```

```
 #### Streaming Pattern
```

```
message ExecuteChunk {
```

```
enum ChunkType {
```

```
 Design Decisions:
 - Sequence numbers for ordering
 - Chunk types for different streams
 - Heartbeats to detect connection issues
 - Final chunk includes error if failed
```

```
 #### Error Handling
```

```
message ExecuteError {
```

```
 Design Decisions:
 - Structured errors (not just strings)
 - Retryable flag for automatic retry logic
 - Stack trace for debugging (not exposed to users)
```

```

```

```
 ## 9. Data Models
```

```
 ### 9.1 Core Types
```

```
 #### ChatSession
```

```
pub struct ChatSession {
```

```
// Authentication
```

```
 Storage Strategy:
 - **Phase 1**: In-memory (RwLock<HashMap>)
 - **Phase 2**: Redis (fast, persistent)
 - **Phase 3**: PostgreSQL (full history, queries)
```

```
 #### ChatMessage
```

```
pub struct ChatMessage {
```

```
pub enum MessageRole {
```

```
 #### ToolCall
```

```
pub struct ToolCall {
```

```
pub struct ToolCallResult {
```

```
 ## 9.2 Execution Tracking
```

```
ExecutionContext
```

```
pub struct ExecutionContext {
```

```
ExecutionResult
```

```
pub struct ExecutionResult {
```

```
Storage: Append-only log in `op-execution-tracker`
```

```
9.3 Metrics
```

```
ExecutorMetrics
```

```
pub struct ExecutorMetrics {
```

```
Aggregation:
```

```
pub struct AggregatedMetrics {
```

```
9.4 Configuration
```

```
ChatActorConfig
```

```
pub struct ChatActorConfig {
```

```
pub struct RateLimitConfig {
```

```
AgentPoolConfig
```

```
pub struct AgentPoolConfig {
```

```
Configuration Sources (priority order):
```

1. Environment variables
2. Configuration file (`/etc/op-dbus/chat.toml`)
3. Defaults

```

```

```
10. Implementation Plan
```

```
10.1 Phase 1: MVP (Weeks 1-4)
```

```
Week 1: Core Infrastructure
```

- [ ] ChatActor with actor pattern
- [ ] SessionManager (in-memory)
- [ ] SystemPromptGenerator
- [ ] Basic RpcRequest/RpcResponse types
- [ ] Unit tests for core components

```
Week 2: Tool Execution
```

- [ ] TrackedToolExecutor
- [ ] Rate limiting implementation
- [ ] Integration with op-execution-tracker
- [ ] Metrics collection
- [ ] Tool execution tests

```
Week 3: Anti-Hallucination
```

- [ ] ForcedExecutionOrchestrator
- [ ] Response tools (respond\_to\_user, cannot\_perform)
- [ ] Hallucination detection (5 types)
- [ ] Verification rules
- [ ] Anti-hallucination tests

```
Week 4: NL Admin
```

- [ ] NLAdminOrchestrator
- [ ] ToolCallParser (4 formats)
- [ ] LLM provider integration
- [ ] End-to-end tests
- [ ] Documentation

```
Deliverable: Working natural language admin with anti-hallucination
```

```
10.2 Phase 2: Agent Orchestration (Weeks 5-8)
```

```
Week 5: gRPC Infrastructure
- [] Protocol definitions (orchestration.proto, agents.proto)
- [] Code generation with tonic-build
- [] Basic gRPC client/server
- [] Connection management
- [] gRPC tests

Week 6: Agent Pool
- [] GrpcAgentPool implementation
- [] Connection pooling
- [] Health checking
- [] Circuit breaker
- [] Pool tests

Week 7: Agent Integration
- [] rust_pro agent
- [] memory agent
- [] sequential_thinking agent
- [] Agent tests
- [] Integration tests

Week 8: Session Lifecycle
- [] Start/end session with agents
- [] Run-on-connection logic
- [] Agent coordination
- [] Lifecycle tests
- [] Documentation

Deliverable: Working agent orchestration with 3 agents

10.3 Phase 3: Workstacks (Weeks 9-12)

Week 9: Workstack Core
- [] Workstack data structures
- [] WorkstackExecutor
- [] Dependency resolution
- [] Variable substitution
- [] Core tests

Week 10: Rollback & Streaming
- [] Rollback implementation
- [] Progress streaming
- [] Condition evaluation
- [] Rollback tests
- [] Streaming tests

Week 11: Built-in Workstacks
- [] rust_project_setup
- [] microservice_deployment
- [] database_migration
- [] Workstack tests
- [] Documentation

Week 12: Workstack Service
- [] WorkstackService gRPC implementation
- [] Status queries
- [] Cancel/rollback operations
- [] Service tests
- [] End-to-end tests

Deliverable: Working workstack system with 3 built-in workflows

10.4 Phase 4: MCP Server (Weeks 13-14)

Week 13: MCP Implementation
- [] ChatMcpServer
- [] Prompts (workstacks)
- [] Resources (skills)
- [] Tools (registry)
- [] MCP tests

Week 14: Standalone Binary
- [] main.rs for standalone server
```

## OP-DBUS / BigPickle

```
- [] Configuration loading
- [] Logging setup
- [] Integration tests
- [] Documentation

Deliverable: Working MCP server

10.5 Phase 5: Polish & Production (Weeks 15-16)

Week 15: Performance
- [] Benchmark suite
- [] Performance optimization
- [] Memory profiling
- [] Load testing
- [] Performance documentation

Week 16: Production Readiness
- [] Comprehensive error handling
- [] Logging and tracing
- [] Metrics dashboard
- [] Deployment guide
- [] Operations runbook

Deliverable: Production-ready op-chat

11. Testing Strategy

11.1 Unit Tests

Coverage Target: 80%

Component Tests
- ChatActor message handling
- SessionManager CRUD operations
- TrackedToolExecutor rate limiting
- ForcedExecutionOrchestrator verification
- GrpcAgentPool connection management
- WorkstackExecutor dependency resolution

Test Structure

#[cfg(test)]

#[tokio::test]

// Execute 60 times (should succeed)

// 61st should fail

11.2 Integration Tests

End-to-End Scenarios
- User: "Create OVS bridge br0"
- Verify: Bridge created, response sent, audit logged

2. **Multi-Step Operation**
- User: "Set up a new Rust project called my-app"
- Verify: Project created, dependencies added, tests written

3. **Hallucination Detection**
- LLM claims action without calling tool
- Verify: Hallucination detected, response blocked

4. **Agent Coordination**
- Execute workstack requiring multiple agents
- Verify: All agents called, results aggregated

5. **Rollback on Failure**
- Workstack fails in phase 3
- Verify: Phases 1-2 rolled back

11.3 Performance Tests
```

```
Load Testing

#[tokio::test]

let mut handles = vec![];

let results = futures::future::join_all(handles).await;
```

```
Benchmark Suite
- Tool execution overhead: < 100ms
- Session creation: < 10ms
- Agent connection: < 100ms
- Workstack execution: < 5s (3-phase)

11.4 Security Tests

Authentication Tests
- Unauthenticated requests rejected
- Controller vs user permissions enforced
- Session isolation verified

Input Validation Tests
- Malformed JSON rejected
- SQL injection attempts blocked
- Path traversal attempts blocked
- Command injection attempts blocked

11.5 Chaos Testing

Failure Scenarios
- Agent crashes mid-operation
- Network partition
- Database unavailable
- LLM provider timeout
- Disk full

Recovery Verification
- Circuit breaker opens
- Automatic reconnection
- Graceful degradation
- No data loss

12. Performance Targets

12.1 Latency

| Operation | Target | Measurement |
|-----|-----|-----|
| Simple tool execution | < 1s | p95 |
| Complex tool execution | < 5s | p95 |
| Session creation | < 10ms | p95 |
| Agent connection | < 100ms | p95 |
| Workstack (3-phase) | < 5s | p95 |
| Health check | < 50ms | p95 |

12.2 Throughput

| Metric | Target |
|-----|-----|
| Concurrent sessions | 100 |
| Requests per second | 1000 |
| Tool executions per second | 500 |
| Agent operations per second | 200 |

12.3 Resource Usage

| Resource | Target |
|-----|-----|
| Memory per instance | < 100MB |
| CPU per instance | < 50% (1 core) |
| Network bandwidth | < 10MB/s |
```

```
| Disk I/O | < 1MB/s |

12.4 Scalability

| Dimension | Target |
|-----|-----|
| Tools in registry | 1000+ |
| Active sessions | 1000+ |
| Message history per session | 10,000+ |
| Concurrent agent connections | 50+ |

12.5 Optimization Strategies

SIMD JSON
- Use `simd-json` instead of `serde_json`
- 2-3x faster parsing
- Critical for high-frequency operations

Connection Pooling
- Reuse gRPC connections
- Avoid connection overhead
- Health checks to detect failures

Async/Await
- Non-blocking I/O
- Efficient resource usage
- Tokio runtime

Caching
- Cache tool definitions
- Cache system prompts
- Cache agent capabilities

13. Security Model

13.1 Authentication

WireGuard Integration

pub struct ChatSession {

Flow:
1. User connects via WireGuard
2. Gateway authenticates and assigns session ID
3. Gateway forwards to op-chat with auth context
4. op-chat creates authenticated session

Unauthenticated Access
- Read-only operations allowed
- Tool execution requires authentication
- System operations require controller role

13.2 Authorization

Role-Based Access Control

| Role | Permissions |
|-----|-----|
| Unauthenticated | List tools, health check |
| User | Execute tools, manage own sessions |
| Controller | All user permissions + manage all sessions, view audit logs |

Implementation

fn check_permission(session: &ChatSession, operation: &str) -> Result<> {

13.3 Audit Trail

What to Log
- All tool executions (who, what, when, result)
- Session creation/deletion
- Authentication events
```

- Authorization failures
- System errors

#### Log Format

```
pub struct AuditEntry {
```

```
pub enum AuditResult {
```

#### Storage

- Append-only log
- Immutable entries
- Indexed by session\_id, timestamp
- Retention: 90 days (configurable)

### 13.4 Input Validation

#### Tool Arguments

```
fn validate_tool_arguments(
```

```
// Type checking
```

```
validate_type(value, ¶m.param_type)?;
```

```
// Value constraints
```

```
Ok()
```

#### Path Traversal Prevention

```
fn validate_path(path: &str) -> Result<()> {
```

```
let canonical = std::fs::canonicalize(path)?;
```

```
Ok()
```

#### Command Injection Prevention

```
fn validate_command(command: &str) -> Result<()> {
```

```
let cmd = command.split_whitespace().next()
```

```
if !ALLOWED_COMMANDS.contains(&cmd) {
```

```
// Check for shell metacharacters
```

```
Ok()
```

### 13.5 Rate Limiting

#### Per-Session Limits

- 60 executions per minute
- 500 executions per hour
- 10 concurrent executions

#### Global Limits

- 1000 requests per second
- 100 concurrent sessions
- 50 concurrent agent connections

#### Implementation

```
struct RateLimiter {
```

```
impl RateLimiter {
```

```
state.check_and_increment(&self.config)?;
```

```
// Check global limit
```

```
Ok()
```

---

## 14. Deployment Architecture

OP-DBUS / BigPickle

```
14.1 Deployment Modes

Mode 1: Standalone (Development)

Use Case: Development, testing, single-user

Mode 2: Distributed (Production)

Use Case: Production, multi-user, high availability

Mode 3: Embedded (Library)

Use Case: Integration into existing applications

14.2 Service Configuration

systemd Unit (op-chat.service)
```

[Unit]  
[Service]

Security

NoNewPrivileges=true

Resource limits

LimitNOFILE=65536

```
[Install]

dinit Service (op-chat)

type = process

14.3 Configuration Files

/etc/op-dbus/chat.toml

[server]

[rate_limit]

[agent_pool]

run_on_connection = [

[tracking]

[logging]

[llm]

/etc/op-dbus/custom-prompt.txt
```

Custom System Prompt Additions

Organization-Specific Rules

- \* Always use staging environment for testing
- \* Require approval for production changes
- \* Follow naming convention: {env}-{service}-{component}

Compliance

- \* Log all PII access
- \* Encrypt sensitive data at rest
- \* Use approved cryptographic algorithms

```
14.4 Monitoring

Metrics Endpoint

// Expose metrics on /metrics

format!(

Health Check Endpoint

async fn health_handler() -> impl IntoResponse {

Json(health)

Prometheus Configuration

scrape_configs:

Grafana Dashboard
- Active sessions over time
- Tool execution rate
- Success/failure ratio
- Average execution time
- Agent health status
- Rate limit hits
- Hallucination detection rate

14.5 Backup & Recovery

Session Backup

#!/bin/bash

redis-cli --rdb /tmp/sessions.rdb

Audit Log Backup

#!/bin/bash

tar -czf /tmp/audit-$(date +%Y%m%d).tar.gz /var/lib/op-chat/audit/

Recovery Procedure
1. Stop op-chat service
2. Restore Redis dump
3. Restore audit logs
4. Verify data integrity
5. Start op-chat service
6. Verify health checks

15. Future Roadmap

15.1 Phase 6: Advanced Features (Q2 2026)

Persistent Sessions
- Redis backend for sessions
- Session migration between instances
- Session replay for debugging
```

```
Advanced Workstacks
- Conditional branching
- Parallel phase execution
- Dynamic phase generation
- Workstack templates

Skills Marketplace
- Community-contributed skills
- Skill versioning
- Skill dependencies
- Skill discovery

15.2 Phase 7: Intelligence (Q3 2026)

Learning System
- Track hallucination patterns
- Adjust system prompt automatically
- Learn from corrections
- Improve intent recognition

Context Management
- Long-term memory across sessions
- Project-specific context
- Team-shared context
- Context search and retrieval

Proactive Assistance
- Suggest optimizations
- Detect potential issues
- Recommend best practices
- Automated maintenance tasks

15.3 Phase 8: Scale (Q4 2026)

Distributed Architecture
- Multi-region deployment
- Agent federation
- Load balancing
- Failover

Performance Optimization
- Tool execution caching
- Predictive agent startup
- Query optimization
- Resource pooling

Enterprise Features
- Multi-tenancy
- SSO integration
- Advanced RBAC
- Compliance reporting

15.4 Research Areas

LLM Improvements
- Fine-tuning for system administration
- Smaller, faster models
- On-device inference
- Multi-modal support (diagrams, logs)

Agent Intelligence
- Autonomous agents
- Agent collaboration
- Agent learning
- Agent specialization

Verification
- Formal verification of critical operations
- Property-based testing
- Chaos engineering
- Fault injection

```

```
16. Risk Analysis

16.1 Technical Risks

Risk: LLM Hallucination
- **Probability**: High
- **Impact**: Critical
- **Mitigation**: Forced tool execution architecture, verification
- **Contingency**: Manual review mode, rollback capability

Risk: Agent Failure
- **Probability**: Medium
- **Impact**: High
- **Mitigation**: Circuit breaker, health checks, graceful degradation
- **Contingency**: Fallback to direct tool execution

Risk: Performance Degradation
- **Probability**: Medium
- **Impact**: Medium
- **Mitigation**: Rate limiting, connection pooling, caching
- **Contingency**: Horizontal scaling, resource limits

Risk: Security Breach
- **Probability**: Low
- **Impact**: Critical
- **Mitigation**: Authentication, authorization, input validation, audit trail
- **Contingency**: Incident response plan, forensics

16.2 Operational Risks

Risk: Configuration Error
- **Probability**: Medium
- **Impact**: High
- **Mitigation**: Configuration validation, defaults, documentation
- **Contingency**: Rollback to previous config, safe mode

Risk: Dependency Failure
- **Probability**: Low
- **Impact**: High
- **Mitigation**: Vendor diversity, fallbacks, monitoring
- **Contingency**: Manual operation mode

Risk: Data Loss
- **Probability**: Low
- **Impact**: High
- **Mitigation**: Backups, replication, append-only logs
- **Contingency**: Recovery procedures, data reconstruction

16.3 Business Risks

Risk: Adoption Resistance
- **Probability**: Medium
- **Impact**: Medium
- **Mitigation**: Documentation, training, gradual rollout
- **Contingency**: Traditional CLI fallback

Risk: Compliance Issues
- **Probability**: Low
- **Impact**: High
- **Mitigation**: Audit trail, data retention, access controls
- **Contingency**: Compliance review, remediation plan

17. Success Criteria

17.1 Technical Success

- [] Hallucination rate < 0.1%
- [] Intent recognition > 95%
- [] Response time < 1s (p95)
- [] Uptime > 99.9%
- [] Zero data loss
- [] 100% audit coverage
```

### ### 17.2 User Success

- [ ] Users prefer NL interface over CLI
- [ ] Reduced time to complete tasks
- [ ] Fewer errors in operations
- [ ] Positive user feedback
- [ ] Active daily usage

### ### 17.3 Business Success

- [ ] Reduced operational costs
- [ ] Faster incident response
- [ ] Improved system reliability
- [ ] Compliance maintained
- [ ] Positive ROI

---

## ## 18. Open Questions

### ### 18.1 Technical Questions

1. **\*\*LLM Provider\*\***: Which provider(s) to support initially?
  - Anthropic (Claude)
  - OpenAI (GPT-4)
  - Local (Ollama)
  - Multiple?
2. **\*\*Session Storage\*\***: When to move from in-memory to persistent?
  - Phase 1: In-memory
  - Phase 2: Redis
  - Phase 3: PostgreSQL
  - Configurable?
3. **\*\*Agent Discovery\*\***: How do agents register themselves?
  - Static configuration
  - Service discovery (Consul, etcd)
  - DNS-based
  - Hybrid?
4. **\*\*Workstack Distribution\*\***: How to share workstacks?
  - Built-in only
  - File-based
  - Registry service
  - Git-based?

### ### 18.2 Design Questions

1. **\*\*Error Recovery\*\***: How aggressive should automatic retry be?
  - Conservative (fail fast)
  - Aggressive (retry everything)
  - Configurable per tool
  - Learn from history?
2. **\*\*Rate Limiting\*\***: Should limits be per-user or per-session?
  - Per-session (current design)
  - Per-user (requires user tracking)
  - Per-tool (different limits per tool)
  - Dynamic (based on load)?
3. **\*\*Streaming\*\***: When to use streaming vs synchronous?
  - Always stream (consistent interface)
  - Stream only for long operations (complexity)
  - Client choice (flexibility)
  - Automatic (based on timeout)?

### ### 18.3 Operational Questions

1. **\*\*Deployment\*\***: How to handle rolling updates?
  - Blue-green deployment
  - Canary deployment
  - Rolling restart
  - Session migration?

```
2. **Monitoring**: What metrics are most important?
- Current: Execution count, time, success rate
- Add: User satisfaction, intent accuracy
- Add: Resource usage, cost
- Add: Business metrics?

3. **Scaling**: When to scale horizontally vs vertically?
- Horizontal: More instances
- Vertical: Bigger instances
- Hybrid: Both
- Auto-scaling rules?

19. Appendices

19.1 Glossary

- **Actor**: Concurrency pattern with message passing
- **Agent**: Specialized service for specific capabilities
- **Circuit Breaker**: Fault tolerance pattern
- **Hallucination**: LLM claiming false information
- **MCP**: Model Context Protocol
- **Workstack**: Multi-phase workflow
- **Tool**: Executable operation
- **Session**: Conversation context

<file path="op-chat/SPEC.md">
op-chat - Comprehensive Specification

Crate: `op-chat`
Location: `crates/op-chat`
Version: Workspace
Edition: Rust 2021
Description: Chat orchestration layer with LLM integration, anti-hallucination architecture, and gRPC agent coordination

Table of Contents

1. [Overview](#overview)
2. [Architecture](#architecture)
3. [Core Components](#core-components)
4. [Orchestration System](#orchestration-system)
5. [Protocol Definitions](#protocol-definitions)
6. [Anti-Hallucination System](#anti-hallucination-system)
7. [Tool Execution](#tool-execution)
8. [Session Management](#session-management)
9. [MCP Server](#mcp-server)
10. [Dependencies](#dependencies)
11. [Build Configuration](#build-configuration)
12. [Usage Examples](#usage-examples)

1. Overview

`op-chat` is the brain of the op-dbus-v2 system. It provides:

- Anti-Hallucination Architecture: Force all LLM output through verified tools
- gRPC Agent Orchestration: Coordinate run-on-connection agents (rust_pro, memory, sequential_thinking, etc.)
- Workstack Execution: Multi-phase workflow orchestration with rollback support
- Skills System: Domain-specific knowledge augmentation
- Session Management: Authenticated chat sessions with WireGuard integration
- MCP Server: Model Context Protocol server over gRPC
- Execution Tracking: Full audit trail with rate limiting

Key Design Principles

1. gRPC-First: All internal agent communication uses gRPC for performance
2. SIMD JSON: Uses `simd-json` instead of `serde_json` for serialization
3. D-Bus Integration: Native D-Bus protocol support (no CLI wrappers)
4. Zero Trust: All LLM claims verified against execution log
5. Streaming Support: Long-running operations stream results
6. Circuit Breaker: Fault tolerance for agent failures

2. Architecture

2.1 High-Level Architecture

2.2 Data Flow

User Request Flow
```

## OP-DBUS / BigPickle

User: "Create OVS bridge br0"

```
2.3 Module Organization
```

op-chat/

```

```

```
3. Core Components
```

```
3.1 ChatActor
```

```
File: `src/actor.rs`
```

The central message processor and coordinator. All requests flow through ChatActor.

```
Key Types
```

```
pub struct ChatActor {

pub struct ChatActorConfig {

pub enum RpcRequest {

pub struct RpcResponse {
```

```
Key Methods
```

```
- `new(config: ChatActorConfig) -> Result<(Self, ChatActorHandle)>` - Create actor and handle
- `run(self) -> Result<()>` - Start actor message loop
- `handle_request(&mut self, req: RpcRequest) -> Result<RpcResponse>` - Process request
```

```
Actor Pattern
```

ChatActor uses Tokio's actor pattern with message passing:

```
- Requests sent via `mpsc::channel`
- Responses returned via `oneshot::channel`
- Single-threaded message processing (no locks needed)
```

```
3.2 SessionManager
```

```
File: `src/session.rs`
```

Manages chat sessions with message history and authentication.

```
Key Types
```

```
pub struct ChatSession {

pub struct SessionManager {
```

```
Key Methods
```

```
- `new() -> Self`
- `create_session() -> String` - Create new session, return ID
- `get_session(&self, id: &str) -> Option<ChatSession>`
- `add_message(&self, session_id: &str, message: ChatMessage)`
- `authenticated(auth_session_id: String, is_controller: bool, peer_pubkey: Option<String>) -> ChatSession`
```

```
3.3 System Prompt Generator
```

```
File: `src/system_prompt.rs`
```

Generates comprehensive system prompts with anti-hallucination rules.

```
Structure
```

System prompt has two parts:

```
1. **FIXED PART** (immutable):
- Anti-hallucination rules
- Forced tool execution architecture
```

```
- Available tools and capabilities
- Forbidden CLI commands
- OVS/D-Bus protocol usage

2. **CUSTOM PART** (mutable):
- Loaded from `/etc/op-dbus/custom-prompt.txt`
- Or `./custom-prompt.txt` (development)
- Or `CUSTOM_SYSTEM_PROMPT` environment variable

Key Functions
```

```
pub fn generate_system_prompt()

pub fn create_session_with_system_prompt()
```

```
Critical Rules in System Prompt
```

YOU MUST USE TOOLS FOR EVERYTHING - INCLUDING RESPONDING TO THE USER.

Workflow:

NEVER:

- \* Output text directly without using respond\_to\_user
- \* Say "I have created..." when you haven't called the tool

\* Claim

```

4. Orchestration System

4.1 Workstacks

File: `src/orchestration/workstacks.rs`

Workstacks define complex, multi-phase workflows that coordinate multiple tools and agents.

Key Types
```

```
pub struct Workstack {

pub struct WorkstackPhase {

pub enum PhaseStatus {

pub struct PhaseToolCall {
```

```
Built-in Workstacks

The `builtin_workstacks()` function provides pre-defined workflows:

1. **rust_project_setup** - Initialize Rust project with best practices
2. **microservice_deployment** - Deploy microservice with monitoring
3. **database_migration** - Safe database schema migration
4. **security_audit** - Comprehensive security analysis
5. **performance_optimization** - Profile and optimize performance
6. **disaster_recovery** - Backup and recovery procedures
7. **ci_cd_pipeline** - Set up CI/CD with testing
8. **monitoring_setup** - Deploy Prometheus + Grafana
9. **load_testing** - Performance load testing
10. **code_review** - Automated code review workflow

4.2 WorkstackExecutor

File: `src/orchestration/workstack_executor.rs`

Executes workstacks with dependency resolution, rollback support, and progress tracking.

Key Types
```

```
pub struct WorkstackExecutor {
```

pub struct WorkstackResult {

#### Execution Flow

1. Validate workstack definition

#### Variable Substitution

Tool arguments can reference variables:

{

### 4.3 Skills System

**File:** `src/orchestration/skills.rs`

Skills provide domain-specific knowledge and capabilities that augment tool execution.

#### Key Types

pub struct Skill {

pub struct SkillMetadata {

pub struct SkillContext {

pub struct SkillConstraint {

pub enum ConstraintType {

#### Built-in Skills

Located in `src/orchestration/skills\_builtin`:

- **architecture\_patterns.md** - System design patterns
- **auth\_implementation\_patterns.md** - Authentication best practices
- **btrfs\_deployment.md** - Btrfs filesystem deployment
- **code\_review\_excellence.md** - Code review guidelines
- **debugging\_strategies.md** - Debugging methodologies
- **distributed\_tracing.md** - Distributed tracing setup
- **e2e\_testing\_patterns.md** - End-to-end testing
- **error\_handling\_patterns.md** - Error handling strategies
- **gitops\_workflow.md** - GitOps deployment patterns
- **k8s\_manifest\_generator.md** - Kubernetes manifest generation
- **microservices\_patterns.md** - Microservices architecture
- **prometheus\_configuration.md** - Prometheus monitoring
- **python\_testing\_patterns.md** - Python testing best practices
- **secrets\_management.md** - Secrets management
- **sql\_optimization\_patterns.md** - SQL query optimization

#### Skill Registry

pub struct SkillRegistry {

impl SkillRegistry {

### 4.4 GrpcAgentPool

**File:** `src/orchestration/grpc\_pool.rs`

Manages persistent gRPC connections to run-on-connection agents with health checks, reconnection, and circuit breaker.

#### Key Types

pub struct GrpcAgentPool {

pub struct AgentPoolConfig {

pub struct AgentConnection {

pub enum AgentStatus {

## OP-DBUS / BigPickle

```
pub enum CircuitState {
```

```
Default Run-on-Connection Agents
```

```
vec![
```

```
Key Methods
```

```
impl GrpcAgentPool {
```

```
pub async fn start_session(&self, session_id: &str) -> Result<Vec<String>>
```

```
pub async fn end_session(&self, session_id: &str) -> Result<()>
```

```
pub async fn execute(
```

```
pub async fn execute_stream(
```

```
pub async fn batch_execute(
```

```
pub async fn health_check(&self, agent_id: &str) -> Result<HealthStatus>
```

```
Circuit Breaker Pattern
```

```
When circuit is Open:
```

- Requests fail immediately without attempting connection
- Reduces load on failing agents
- Allows time for recovery

```

```

```
5. Protocol Definitions
```

```
5.1 Orchestration Protocol
```

```
File: `proto/orchestration.proto`
```

```
Full gRPC service definitions for agent communication.
```

```
Services
```

```
AgentLifecycle Service
```

```
service AgentLifecycle {
```

```
AgentExecution Service
```

```
service AgentExecution {
```

```
MemoryService
```

```
service MemoryService {
```

```
SequentialThinkingService
```

```
service SequentialThinkingService {
```

```
ContextManagerService
```

```
service ContextManagerService {
```

```
RustProService
```

```
service RustProService {
```

```
BackendArchitectService
```

```
service BackendArchitectService {
```

```
WorkstackService
```

```
service WorkstackService {
```

```
5.2 Internal Agent Protocol
```

```
File: `proto/agents.proto`
```

Simplified protocol for chatbot-to-agent communication.

```
Services
```

```
service AgentService {
```

```
Individual agent services:
```

```
- `MemoryAgent`
- `SequentialThinkingAgent`
- `ContextManagerAgent`
- `RustProAgent`
- `BackendArchitectAgent`
```

```

```

```
6. Anti-Hallucination System
```

```
6.1 ForcedExecutionOrchestrator
```

```
File: `src/forced_execution.rs`
```

Ensures the LLM cannot hallucinate by requiring all output to go through verified tools.

```
Architecture
```

```
Key Types
```

```
pub struct ForcedExecutionOrchestrator {
```

```
pub struct HallucinationCheck {
```

```
pub struct HallucinationIssue {
```

```
pub enum HallucinationType {
```

```
pub enum IssueSeverity {
```

```
pub struct ToolCall {
```

```
pub struct ToolCallResult {
```

```
Key Methods
```

```
impl ForcedExecutionOrchestrator {
```

```
pub async fn start_turn(&self)
```

```
pub async fn execute_and_verify(
```

```
pub async fn verify_response(
```

```
Verification Rules
```

1. **No Raw Text Output**: All LLM output must go through `respond\_to\_user` tool
2. **Action Verification**: Any claimed action must have corresponding tool execution
3. **Response Tool Required**: Every turn must call `respond\_to\_user`
4. **Success Verification**: Cannot claim success if tool execution failed
5. **Reference Integrity**: `respond\_to\_user` must reference actual executed tools

```
Helper Functions
```

```
pub fn parse_tool_calls(llm_response: &Value) -> Vec<ToolCall>
```

```
pub fn detect_raw_text_output(llm_response: &Value) -> Option<String>
```

```
6.2 Response Tools

Response tools are special tools that the LLM MUST use to communicate with users.

respond_to_user

{

cannot_perform

{

6.3 Hallucination Detection Examples

Example 1: Raw Text Output (CRITICAL)

// LLM Response
// Detection Result

Example 2: Unverified Action Claim (ERROR)

// LLM Response
// But ovs_create_bridge was never called!
// Detection Result

Example 3: Verified Response (SUCCESS)

// LLM Response
// Execution: ovs_create_bridge succeeded
// Detection Result

7. Tool Execution

7.1 TrackedToolExecutor

File: `src/tool_executor.rs`

Wraps tool execution with tracking, rate limiting, and metrics.

Key Types

pub struct TrackedToolExecutor {
pub struct RateLimitConfig {
struct SessionRateState {
struct ExecutorMetrics {

Key Methods

impl TrackedToolExecutor {
pub async fn execute(
pub async fn execute_sequence(
pub async fn get_metrics(&self) -> ExecutorMetrics
async fn check_rate_limit(&self, session_id: &str) -> Result<()>

Execution Flow
```

## OP-DBUS / BigPickle

1. Check rate limit for session
2. Acquire concurrent execution permit
3. Create execution context
4. Execute tool via ToolRegistry
5. Record execution in tracker
6. Update metrics
7. Release permit and return result

### #### Rate Limiting

Rate limits are per-session with sliding windows:

- **Per-minute window**: Resets every 60 seconds
- **Per-hour window**: Resets every 3600 seconds

When limit exceeded:

Err("Rate limit exceeded: 60 executions per minute")

### #### Metrics

```
pub struct ExecutorMetrics {
```

### ### 7.2 Integration with ExecutionTracker

TrackedToolExecutor integrates with `op-execution-tracker` for full audit trail:

```
let context = ExecutionContext {
```

```
let result = ExecutionResult {
```

```
tracker.record(context, result).await?;
```

```

```

## ## 8. Session Management

### ### 8.1 ChatSession

**File**: `src/session.rs`

### #### Session Lifecycle

1. Create Session
2. Add Messages
3. Update Metadata
4. Authentication (Optional)
5. Session End

### #### Key Methods

```
impl ChatSession {
```

```
pub fn with_id(id: impl Into<String>) -> Self
```

```
pub fn authenticated(
```

```
pub fn add_message(&mut self, message: ChatMessage)
```

```
pub fn get_messages(&self) -> &[ChatMessage]
```

```
pub fn set_metadata(&mut self, key: String, value: Value)
```

OP-DBUS / BigPickle

pub fn get\_metadata(&self, key: &str) -> Option<&Value>

### 8.2 SessionManager

#### Key Methods

```
impl SessionManager {

pub async fn create_session(&self) -> String

pub async fn get_session(&self, id: &str) -> Option<ChatSession>

pub async fn add_message(

pub async fn list_sessions(&self) -> Vec<String>

pub async fn delete_session(&self, id: &str) -> Result<()>

pub async fn cleanup_old_sessions(&self, max_age: Duration) -> usize
```

### 8.3 WireGuard Integration

Sessions can be authenticated via WireGuard gateway:

let session = ChatSession::authenticated(

Controller sessions have elevated privileges:

- Can manage other sessions
- Can access system-level operations
- Can view audit logs

---

## 9. Natural Language Administration

### 9.1 NlAdminOrchestrator

**File:** `src/nl\_admin.rs`

The core module that enables natural language server administration.

#### Architecture

User Input: "Create an OVS bridge called br0"

#### Key Types

```
pub struct NlAdminOrchestrator {

pub struct NlAdminResult {

pub struct ToolExecutionResult {

pub struct ExtractedToolCall {

pub enum ToolCallSource {
```

#### Key Methods

```
impl NlAdminOrchestrator {

pub async fn process(

async fn extract_tool_calls(

async fn execute_tools(

```

#### Processing Flow

1. Build System Prompt

## OP-DBUS / BigPickle

2. Prepare LLM Request
3. Call LLM Provider
4. Extract Tool Calls
5. Execute Tools
6. Format Response

### ### 9.2 ToolCallParser

Extracts tool calls from various LLM response formats.

#### #### Supported Formats

##### ##### 1. Native Tool Calls (Preferred)

```
{
```

##### ##### 2. XML Tags

```
<tool_call>ovs_create_bridge({"name": "br0"})</tool_call>
```

##### ##### 3. Code Blocks

```
ovs_create_bridge({"name": "br0"})
```

```
respond_to_user({"message": "Created bridge br0"})
```

##### ##### 4. JSON in Text

I will call ovs\_create\_bridge({"name": "br0"}) to create the bridge.

#### #### Parser Implementation

```
pub struct ToolCallParser {
 impl ToolCallParser {
 pub fn parse(&self, text: &str) -> Vec<ExtractedToolCall>
 fn parse_xml_tags(&self, text: &str) -> Vec<ExtractedToolCall>
 fn parse_code_blocks(&self, text: &str) -> Vec<ExtractedToolCall>
 fn parse_function_calls(&self, text: &str) -> Vec<ExtractedToolCall>
```

### ### 9.3 Response Formatting

The `respond\_to\_user` tool accumulates responses:

```
// In op-tools/src/builtin/response_tools.rs
pub fn get_response_accumulator() -> Arc<RwLock<Vec<String>>>
pub async fn clear_response_accumulator()
```

After tool execution:

```
let responses = get_response_accumulator().read().await;
```

```

```

## ## 10. MCP Server

### ### 10.1 ChatMcpServer

**File:** `src/mcp\_server.rs`

Exposes chat capabilities as a Model Context Protocol (MCP) server over gRPC.

#### #### Architecture

```
MCP Protocol Support

The server implements MCP via the generic `call` tunnel for JSON-RPC:

Prompts
- `prompts/list` - List available workstacks
- `prompts/get` - Get workstack details

Resources
- `resources/list` - List available skills and documentation
- `resources/read` - Read skill content

Tools
- `tools/list` - List all registered tools
- `tools/call` - Execute a tool

Key Types
```

```
pub struct ChatMcpServer {

#[derive(Debug, Serialize, Deserialize)]

#[derive(Debug, Serialize, Deserialize)]
```

#### Implementation

```
#[tonic::async_trait]

async fn health(

async fn list_tools(

async fn call_tool(

async fn call(

async fn subscribe(
```

#### Running the Server

```
pub async fn run_chat_mcp_server(

Server::builder()

Ok()
```

#### Standalone Binary

```
File: `src/main.rs`
```

```
#[tokio::main]

let addr: SocketAddr = std::env::var("OP_CHAT_LISTEN")

let config = ChatActorConfig::default();

println!("Starting op-chat MCP server on {}", addr);

Ok()
```

Usage:

Default: 0.0.0.0:50052

cargo run --bin op-chat

Custom address

## OP-DBUS / BigPickle

OP\_CHAT\_LISTEN=127.0.0.1:8080 cargo run --bin op-chat

```

11. Dependencies

11.1 Workspace Dependencies

tokio = { workspace = true, features = ["full"] }

11.2 D-Bus Support

zbus = { workspace = true }

11.3 gRPC Support

tonic = { workspace = true }

11.4 Internal Dependencies

op-core = { path = "../op-core" }

11.5 Dev Dependencies

[dev-dependencies]

11.6 Build Dependencies

[build-dependencies]

12. Build Configuration

12.1 build.rs

File: `build.rs`

Compiles protobuf definitions using `tonic-build`:

fn main() -> Result<(), Box<dyn std::error::Error>> {
 Ok(())
}

Generated files:
- `src/orchestration/proto/op_chat.orchestration.rs`
- `src/orchestration/proto/op_chat.agents.rs`

12.2 Cargo Features

Currently no features defined. All functionality is enabled by default.

12.3 Build Commands
```

## Development build

cargo build

## Release build

cargo build --release

## Build with verbose output

cargo build -vv

## Check without building

cargo check

## Run tests

cargo test

## Run clippy

cargo clippy

## Format code

cargo fmt

```

13. Usage Examples

13.1 Creating a ChatActor

use op_chat::{ChatActor, ChatActorConfig};

#[tokio::main]

let (actor, handle) = ChatActor::new(config).await?;

// Spawn actor task

// Use handle to send requests

Ok()
```

```
13.2 Sending a Chat Request
```

```
use op_chat::RpcRequest;

let request = RpcRequest::Chat {

let response = handle.send(request).await?;

if response.success {
```

```
13.3 Executing a Tool
```

```
use simd_json::json;

let request = RpcRequest::ExecuteTool {

let response = handle.send(request).await?;
```

```
13.4 Using NLAdminOrchestrator
```

```
use op_chat::NLAdminOrchestrator;

let orchestrator = NLAdminOrchestrator::new(

let result = orchestrator.process(

```

**OP-DBUS / BigPickle**

```
println!("{}", result.success);
```

### 13.5 Executing a Workstack

```
use op_chat::orchestration::{WorkstackExecutor, builtin_workstacks};

let workstacks = builtin_workstacks();

let executor = WorkstackExecutor::new(tool_executor, agent_pool);

let result = executor.execute(

println!("{}", result.success);
```

### 13.6 Using the GrpcAgentPool

```
use op_chat::orchestration::{GrpcAgentPool, AgentPoolConfig};

let config = AgentPoolConfig::default();

// Start session (starts run-on-connection agents)

// Execute on an agent

// End session (cleanup)
```

### 13.7 Verifying Against Hallucination

```
use op_chat::ForcedExecutionOrchestrator;

let orchestrator = ForcedExecutionOrchestrator::new(executor);

orchestrator.start_turn().await;

let (results, check) = orchestrator.execute_and_verify(

if !check.verified {
```

### 13.8 Running the MCP Server

**Start the server**

```
cargo run --bin op-chat
```

**Or with custom address**

```
OP_CHAT_LISTEN=127.0.0.1:8080 cargo run --bin op-chat
```

Connect from MCP client:

```
{
```

---

## 14. Testing

### 14.1 Unit Tests

Each module includes unit tests:

```
#[cfg(test)]
```

```
#[tokio::test]
```

Run tests:

```
cargo test
```

### ### 14.2 Integration Tests

Integration tests would go in `tests/` directory (not currently present).

### ### 14.3 Test Coverage

Key areas to test:

- Tool execution and tracking
- Rate limiting
- Hallucination detection
- Session management
- Workstack execution
- Agent pool connection management
- MCP protocol compliance

---

## ## 15. Performance Considerations

### ### 15.1 SIMD JSON

Uses `simd-json` for faster JSON parsing:

- 2-3x faster than `serde\_json`
- SIMD instructions for parsing
- Important for high-frequency tool execution

### ### 15.2 gRPC for Agent Communication

- Binary protocol (faster than JSON-RPC)
- HTTP/2 multiplexing
- Streaming support for long operations
- Connection pooling

### ### 15.3 Connection Pooling

GrpcAgentPool maintains persistent connections:

- Avoid connection overhead
- Health checks to detect failures
- Automatic reconnection

### ### 15.4 Rate Limiting

Prevents resource exhaustion:

- Per-session limits
- Global concurrent execution limit
- Sliding window algorithm

### ### 15.5 Async/Await

Fully async architecture:

- Non-blocking I/O
- Efficient resource usage
- Tokio runtime

---

## ## 16. Security Considerations

### ### 16.1 Tool Execution Tracking

All tool executions are logged:

- Who executed (session ID)
- What was executed (tool name + args)
- When (timestamp)
- Result (success/failure)

### ### 16.2 Rate Limiting

Prevents abuse:

- Per-session limits
- Cannot exhaust system resources
- Configurable thresholds

### ### 16.3 Anti-Hallucination

Prevents LLM from claiming false actions:

- All claims verified against execution log
- Cannot bypass tool execution
- Forced response tools

### 16.4 WireGuard Authentication

Sessions can be authenticated:

- Cryptographic peer identity
- Controller vs regular user roles
- Audit trail with peer public key

### 16.5 Input Validation

Tool arguments validated before execution:

- Type checking
- Required fields
- Value constraints

---

## 17. Future Enhancements

### 17.1 Planned Features

- [ ] Persistent session storage (database)
- [ ] Workstack templates and customization
- [ ] Skill marketplace
- [ ] Agent hot-reload
- [ ] Distributed agent pool (multi-host)
- [ ] Advanced metrics and monitoring
- [ ] Workstack visualization
- [ ] Interactive debugging mode

### 17.2 Performance Improvements

- [ ] Tool execution caching
- [ ] Parallel phase execution in workstacks
- [ ] Lazy agent initialization
- [ ] Response streaming to client

### 17.3 Protocol Enhancements

- [ ] WebSocket support for MCP
- [ ] GraphQL API
- [ ] REST API fallback
- [ ] Batch tool execution API

---

## 18. Troubleshooting

### 18.1 Common Issues

#### Agent Connection Failures

Error: Failed to connect to agent rust\_pro

**\*\*Solution\*\*:** Check that agent is running and address is correct:

## Check agent status

netstat -tlnp | grep 50051

## Check logs

journalctl -u op-agent-rust-pro

#### Rate Limit Exceeded

Error: Rate limit exceeded: 60 executions per minute

**Solution:** Increase rate limits in config:

```
let config = ChatActorConfig {
```

#### Hallucination Detected

Warning: Hallucination detected - UnverifiedActionClaim

**Solution:** This is working as intended. The LLM tried to claim an action without executing it. The system prevented the hallucination.

### 18.2 Debugging

Enable debug logging:

RUST\_LOG=op\_chat=debug cargo run

Enable trace logging:

RUST\_LOG=op\_chat=trace cargo run

### 18.3 Performance Profiling

## CPU profiling

cargo flamegraph --bin op-chat

## Memory profiling

cargo valgrind --bin op-chat

```

19. Contributing

19.1 Code Style

Follow repository guidelines in `/AGENTS.md`:
- `rustfmt` defaults
- `cargo clippy` clean
- Comprehensive error handling
- Tracing for observability

19.2 Adding New Workstacks

1. Define workstack in `src/orchestration/mod.rs`
2. Add to `builtin_workstacks()` function
3. Document phases and dependencies
4. Add tests

19.3 Adding New Skills

1. Create markdown file in `src/orchestration/skills_builtin/`
2. Define skill metadata
3. Register in skill registry
4. Document usage

19.4 Adding New Agents

1. Define protobuf service in `proto/orchestration.proto`
2. Implement agent service
3. Add to `run_on_connection` list
4. Document operations

```

## ## 20. References

### ### 20.1 Related Crates

- `op-core` - Core types and utilities
- `op-tools` - Tool registry and execution
- `op-llm` - LLM provider abstraction
- `op-execution-tracker` - Execution audit trail
- `op-agents` - Agent implementations
- `op-mcp` - MCP protocol implementation

//! Context-Aware MCP Client Example

//!

//! Demonstrates how to use the proactive knowledge push feature

//! of the cognitive-mcp server with SSE streaming.

//!

//! ## Features Demonstrated

//!

//! 1. **\*\*SSE Stream Connection\*\*** - Subscribe to `/context/stream/:session\_id`

//! 2. **\*\*Activity Recording\*\*** - Report user activity for context tracking

//! 3. **\*\*Proactive Receives\*\*** - Handle knowledge pushes triggered by:

//! - New topic detection

//! - Stuck session patterns

//! - Error assistance

//! - Idle recovery

//! 4. **\*\*On-Demand Push\*\*** - Request knowledge when needed

//!

//! ## Running

//!

//! ```bash

//! cargo run --example context\_aware\_client -- --session-id my-session-1

//! ```

use clap::Parser;

use futures::StreamExt;

use request::Client;

use serde\_json::json;

use std::time::Duration;

 //! Cognitive MCP External Client Example
 //!
 //! Demonstrates how external clients (Droid, Cursor, Codex, NotebookLM, Gemini CLI)
 //! should connect to cognitive-mcp on port 3003 per AGENTS.md specification.
 //!
 //! ## Architecture Compliance
 //!
 //! Per AGENTS.md Section 4b:
 //! - **cognitive-mcp** (`:3003`, Netmaker WG IP `100.90.37.254`) is the **universal

```

## OP-DBUS / BigPickle

```
#!/ gateway for ALL external clients**
#!/ - **compact-mcp** (`127.0.0.1:11436`) is **loopback/chatbot only**
#!/
#!/ ## Usage
#!/
#!/ ```bash
#!/ # Run with external client configuration (correct)
#!/ cargo run --example external_client -- --client-type droid
#!/
#!/ # Run with local chatbot configuration (loopback only)
#!/ cargo run --example external_client -- --client-type local
#!/ ```

 //! Cognitive MCP Client Configuration & Optimization
 //!
 //! Provides connection pooling, caching, retry logic, and optimized transport
 //! patterns for external MCP clients connecting to the cognitive-mcp gateway.
 //!
 //! ## Architecture
 //!
 //! - **cognitive-mcp** (`3003`, Netmaker WG IP `100.90.37.254`):
 //! Universal gateway for ALL external clients: NotebookLM, Droid, Cursor,
 //! Codex, Junie, Gemini CLI. External clients MUST use this endpoint.
 //!
 //! - **compact-mcp** (`127.0.0.1:11436`):
 //! Loopback/chatbot only. NEVER expose externally.
 //!
 //! ## Client Optimization Strategies
 //!
 //! 1. **Connection Pooling**: Reuse HTTP/SSE connections to reduce latency
 //! 2. **Capability Caching**: Cache tool/resource discovery to reduce round-trips
 //! 3. **Batched Operations**: Parallelize independent tool calls
 //! 4. **Circuit Breaker**: Fail-fast on degraded service
 //! 5. **Exponential Backoff**: Graceful retry with jitter
 //!
 //! ## Usage
 //!
 //! ```rust
 //! use op_cognitive_mcp::client_config::{CognitiveMcpClient, ClientConfig};
 //!
 //! let config = ClientConfig::for_external_client("droid-instance-1");
 //! let client = CognitiveMcpClient::connect(config).await?;
 //!
 //! // Cached tool discovery
 //! let tools = client.list_tools_cached().await?;
 //!
 //! // Batched execution
 //! let results = client.call_tools_batch([
 //! ("memory/store", json!({"key": "ctx", "value": "data"})),
 //! ("rag/search", json!({"query": "architecture"})),
 //!].await?;

```

```

compare-op-cognitive-mcp

Date: 2026-04-05
Spec files analyzed: SPEC.md
Analysis mode: Current system state specification with spec-alignment notes

Summary

| Category | Count |
|---|---|
| Rust source files | 6 |
| Proto files | 0 |
| Binary targets | 1 |
| UI files | 0 |
| Root-declared modules | 4 |
| Partial artifacts | 0 |
| Spec-listed source files | 5 |
| Spec-listed but missing | 0 |
| Extra implementation files | 1 |

Current Implementation Overview

- Internal crate integrations: op-core, op-mcp, op-state-store, op-dynamic-loader, op-cache.

Module / File Comparison

| Module or File | State | Current Role | Notes |
|---|---|---|---|

Feature / Capability Comparison

| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
- `op-core` - documented in SPEC
- `op-mcp` - documented in SPEC
- `op-state-store` - not listed in SPEC dependency block
- `op-dynamic-loader` - documented in SPEC
- `op-cache` - documented in SPEC

External Runtime Dependencies
- `serde` - documented in SPEC
- `serde_json` - not listed in SPEC dependency block
- `simd-json` - documented in SPEC
- `tokio` - documented in SPEC
- `anyhow` - documented in SPEC
- `tracing` - documented in SPEC
- `tracing-subscriber` - not listed in SPEC dependency block
- `axum` - documented in SPEC
- `tower` - documented in SPEC
- `tower-http` - documented in SPEC
- `uuid` - documented in SPEC
- `chrono` - documented in SPEC
- `async-trait` - documented in SPEC
- `clap` - not listed in SPEC dependency block
- `sqlx` - not listed in SPEC dependency block
```

```
Development and Build Dependencies
- None

Notes and Observations

- Local documentation files present: SPEC.md.
- Current implementation contains 1 Rust source files beyond the explicit spec/design source inventory.
- Root module declarations found in `lib.rs`/`main.rs`: activity_filter, cognitive_tools, memory_store, server.
- 5 runtime dependencies are present in `Cargo.toml` but omitted from the SPEC dependency block.
</file>

Main Modules
cognitive_tools
memory_store
server

Purpose

`op-cognitive-mcp` exposes code-aware retrieval over the Qdrant/Voyage indexes
used by local coding clients. Retrieval is intentionally split by embedding
space:

- Rust solo: `rust_lang_rust_lsp_voyage_code_3`, queried with `voyage-code-3`
 when `COGNITIVE_MCP_VOYAGE_MODEL=voyage-code-3`.
- Other LSP/spec groups: `repos_lsp_*_voyage_4_lite` and
 `repos_specs_docs_voyage_4_lite`, queried with the Voyage 4 family. These
 default to `voyage-4` at query time and are compatible with
 `voyage-4-lite` indexes.

For context-aware completion, the MCP path should ask Kiro/LSP for exact local
symbol and hover context first, then call `code_context` with
`retrieval_mode="completion"`. Completion retrieval embeds the query once,
```

queries the compatible configured collections, returns top-k vector hits, and does not rerank unless `COGNITIVE\_MCP\_RERANK\_MODE=always`.

Deep chat/edit context can use `retrieval\_mode="deep"` with a larger fetch window. Rerank is only enabled for deep mode when `COGNITIVE\_MCP\_RERANK\_MODE=auto` or `always`.

### Vector Environment

COGNITIVE\_MCP\_VOYAGE\_API\_KEY=<key>

Fall

COGNITIVE\_MCP\_COMPLETION\_COLLECTIONS=repos\_lsp\_c\_cpp\_voyage\_4\_lite,repos\_lsp\_go\_voyage\_4\_lite,repos\_lsp\_java\_voyage\_4\_lite,repos\_lsp\_python\_voyage\_4\_lite,repos\_lsp\_typescript\_voyage\_4\_lite,repos\_specs\_docs\_voyage\_4\_lite

```

Spec files analyzed: SPEC.md
Analysis mode: Current system state specification with spec-alignment notes

Summary

| Category | Count |
|---|---|
| Rust source files | 10 |
| Proto files | 0 |
| Binary targets | 0 |
| UI files | 0 |
| Root-declared modules | 7 |
| Partial artifacts | 1 |
| Spec-listed source files | 9 |
| Spec-listed but missing | 0 |
| Extra implementation files | 1 |

Current Implementation Overview

- Core types and utilities for op-dbus-v2
- Internal crate integrations: op-execution-tracker.

Module / File Comparison

| Module or File | State | Current Role | Notes |
|---|---|---|---|

Feature / Capability Comparison

| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
```

```
- `op-execution-tracker` - documented in SPEC

External Runtime Dependencies
- `async-trait` - not listed in SPEC dependency block
- `serde` - documented in SPEC
- `simd-json` - documented in SPEC
- `uuid` - documented in SPEC
- `chrono` - documented in SPEC
- `tokio` - documented in SPEC
- `tracing` - documented in SPEC
- `thiserror` - documented in SPEC
- `anyhow` - documented in SPEC
- `zbus` - documented in SPEC

Development and Build Dependencies
- `dev:tokio`

Notes and Observations

- Local documentation files present: SPEC.md.
- Transitional or partial artifacts detected: src/lib.rs.patch.
- Current implementation contains 1 Rust source files beyond the explicit spec/design source inventory.
- Root module declarations found in `lib.rs`/`main.rs`: config, error, execution, security, self_identity, state_publisher, types.
- 1 runtime dependencies are present in `Cargo.toml` but omitted from the SPEC dependency block.
</file>

//!
//! Provides a D-Bus interface (`org.opdbus.v1.S6.Systemctl`) that resolves
//! systemd deficiencies by translating systemd concepts to s6 equivalents:
//!
//! | systemd concept | s6 runtime resolution |
//! |-----|-----|
//! | `.service` | s6-rc supervised service |
//! | `.timer` | s6-cron job or s6-tcpserver |
//! | `.socket` | s6-socketmux or s6-ipcserver |
//! | `.target` | s6-rc bundle (grouping) |
//! | `.mount` | mount command + s6-rc oneshot |
//! | `.device` | udev / sysfs check |
//! | `.path` | s6-fstrig or inotify |
//! | `journalctl` | s6-log + s6-logwatch |
//! | `systemctl` | s6-rc / s6-svc / s6-svstat |
//!
//! and the service resolves the deficiency by invoking the correct s6
//! primitive underneath.
//!
//! D-Bus interface: org.opdbus.v1.S6.Systemctl
//! Object path: /org/opdbus/v1/plugins/s6/systemctl

<file path="op-dbus-model/SPEC.md">
op-dbus-model - Specification

Overview
Crate: `op-dbus-model`
Location: `crates/op-dbus-model`
Version: 0.1.0
Edition: 2021

Purpose

The `op-dbus-model` crate provides the core data models and database schema management for the operation-dbus system. It defines t

This crate serves as the foundational data layer that enables:
- Plugin registration and lifecycle tracking
- Schema discovery and versioning
- Metadata persistence for D-Bus services
- Historical tracking of interface definitions

Architecture

Database Layer
- **Backend**: SQLite via sqlx
- **Runtime**: Tokio async runtime
- **Schema Management**: Automated table creation and migration

Data Models

Plugin Model
Represents a registered D-Bus plugin/service in the system.
```

```
pub struct Plugin {

Database Schema:

CREATE TABLE plugins (
```

## OP-DBUS / BigPickle

```
Schema Model
Represents a discovered D-Bus interface schema.
```

```
pub struct Schema {
```

```
 Database Schema:
```

```
 CREATE TABLE schemas (
```

```
 ## Key Components
```

```
 ### Schema Creation
```

```
 pub async fn create_schema(pool: &SqlitePool) -> Result<()>
```

```
 Initializes the database schema with all required tables. This function is idempotent and safe to call multiple times.
```

```
 Features:
 - Creates `plugins` table for service registration
 - Creates `schemas` table for interface definitions
 - Establishes foreign key relationships
 - Automatic timestamp management
```

```
 ## Dependencies
```

```
 ### Core Dependencies
 - **sqlx** (0.8): Async SQL toolkit with SQLite support
 - Features: `runtime-tokio`, `sqlite`, `json`
 - **serde** (1.0): Serialization framework
 - Features: `derive`
 - **simd-json**: High-performance JSON handling
 - **chrono** (0.4): Date and time handling
 - Features: `serde`
 - **uuid** (1.6): Unique identifier generation
 - Features: `v4`, `serde`
```

```
 ### Error Handling
 - **thiserror** (1.0): Derive macros for error types
 - **anyhow** (1.0): Flexible error handling
```

```
 ### Internal Dependencies
 - **op-core**: Core types and utilities
```

```
 ## Usage
```

```
 ### Initialization
```

```
 use op_dbus_model::create_schema;
```

```
 // Connect to database
```

```
 // Initialize schema
```

```
 ### Working with Models
```

```
 use op_dbus_model::models::{Plugin, Schema};
```

```
 // Create a plugin record
```

```
 // Create a schema record
```

```
 ## Integration Points
```

```
 ### Plugin Registration Flow
 1. Plugin discovered via D-Bus introspection
 2. Plugin metadata stored in `plugins` table
 3. Interface schemas extracted and stored in `schemas` table
 4. Foreign key maintains relationship between plugin and schemas
```

```
 ### Schema Discovery Flow
 1. D-Bus interface introspected
```

## OP-DBUS / BigPickle

```
2. Schema definition serialized to JSON
3. Schema record created with discovery metadata
4. Linked to parent plugin via `plugin_name`

Data Integrity

Referential Integrity
- Foreign key constraint ensures schemas reference valid plugins
- Cascade behavior can be configured for plugin deletion

Timestamp Tracking
- `created_at`: Automatic timestamp on record creation
- `discovered_at`: Manual timestamp for schema discovery events

JSON Storage
- `base_object`: Flexible storage for object path configurations
- `definition`: Complete interface definition with methods, signals, properties

Performance Considerations

- **SQLite**: Suitable for single-node deployments
- **Connection Pooling**: Managed by sqlx for concurrent access
- **JSON Indexing**: Consider adding indexes on JSON fields for large datasets
- **Async Operations**: Non-blocking database access via tokio

Future Enhancements

- Schema versioning and migration tracking
- Plugin dependency management
- Schema validation and compatibility checking
- Query builders for common access patterns
- Migration to PostgreSQL for distributed deployments

Core data models and persistence layer for operation-dbus

op-deployment - Specification

Overview
Crate: `op-deployment`
Location: `crates/op-deployment`
Description: Container and image deployment management

Purpose

The `op-deployment` crate provides a sophisticated BTRFS-based deployment image management system with intelligent deduplication.

This crate is critical for:
- **Deployment Orchestration**: Managing deployment artifacts and versions
- **Storage Efficiency**: Deduplicating common files across deployment images
- **Snapshot Management**: Creating BTRFS snapshots for atomic deployments
- **Streaming Deployments**: Preparing images for efficient network transfer

Architecture

BTRFS Integration
The system leverages BTRFS filesystem features:
- **Snapshots**: Atomic, copy-on-write snapshots for each deployment image
- **Deduplication**: Symlink-based deduplication across image versions
- **Streaming**: Efficient snapshot streaming for remote deployments

Directory Structure
```

base\_path/

```
Key Components

ImageManager
Core component for managing deployment images.
```

```
pub struct ImageManager {

 Key Methods:
 - `new(base_path)` : Create new image manager instance
 - `init()` : Initialize directory structure and verify BTRFS
 - `create_image(name, files)` : Create new deployment image with deduplication
 - `is_btrfs(path)` : Check if path is on BTRFS filesystem

 ### ImageMetadata
 Metadata for a deployment image.
```

```
pub struct ImageMetadata {

 Metrics:
 - `total_size` : Sum of all file sizes in the image
 - `unique_size` : Storage actually consumed by new files
```

## OP-DBUS / BigPickle

```
- `symlinked_size`: Storage saved through deduplication
```

```
FileEntry
```

```
Represents a file within a deployment image.
```

```
pub struct FileEntry {
```

```
Deduplication Strategy
```

```
Hash-Based Deduplication
```

1. **Hash Calculation**: SHA256 hash computed for each file
2. **Previous Image Scan**: Check if hash exists in prior images
3. **Symlink Creation**: If match found, create symlink instead of copying
4. **New File Copy**: If no match, copy file normally

```
Benefits
```

- **Storage Efficiency**: Dramatically reduces disk usage for similar images
- **Fast Creation**: Symlinking is faster than copying
- **Version Tracking**: Maintains clear lineage between image versions

```
Example
```

Image v1:

Image v2:

Total storage: 150MB instead of 200MB

```
Dependencies
```

```
Core Dependencies
```

- **tokio**: Async runtime for non-blocking I/O
- **serde**: Serialization for metadata
- **simd-json**: High-performance JSON handling
- **anyhow**: Error handling with context
- **thiserror**: Custom error types

```
Filesystem Operations
```

- **tar**: Archive creation for image packaging
- **flate2**: Compression for efficient transfer
- **sha2**: SHA256 hashing for deduplication

```
Utilities
```

- **reqwest**: HTTP client for remote image operations
- **chrono**: Timestamp management
- **uuid**: Unique identifiers for images
- **tracing/log**: Structured logging

```
Development
```

- **tempfile**: Temporary directories for testing

```
Usage
```

```
Initialization
```

```
use op_deployment::ImageManager;
```

```
#[tokio::main]
```

```
// Initialize directory structure
```

```
Ok()
```

```
Creating a Deployment Image
```

```
use std::path::PathBuf;
```

```
// Prepare files for deployment
```

```
// Create deployment image
```

```
println!("Image created: {}", metadata.name);
```

## OP-DBUS / BigPickle

```
Creating Incremental Updates
```

```
// Create v2 with mostly same files
```

```
let metadata_v2 = manager.create_image("my-service-v2", files_v2).await?;
```

```
// Most files symlinked, only new files consume storage
```

```
BTRFS Snapshot Workflow
```

```
Snapshot Creation
```

1. Image directory created with files
2. BTRFS snapshot taken of image directory
3. Snapshot stored in `snapshots/` for streaming

```
Snapshot Streaming
```

1. BTRFS send command generates snapshot stream
2. Stream can be piped over network
3. Remote system receives with BTRFS receive
4. Atomic deployment on target system

```
Fallback Behavior
```

```
If not on BTRFS:
```

- Images still created with deduplication
- Snapshots disabled (warning logged)
- Standard tar/gzip used for transfer

```
Performance Considerations
```

```
Filesystem Requirements
```

- **BTRFS Recommended**: Full feature set with snapshots
- **Other Filesystems**: Deduplication works, snapshots disabled

```
Deduplication Overhead
```

- **Hash Calculation**: SHA256 computed once per file
- **Lookup Cost**: O(n) scan of previous images
- **Optimization**: Consider hash index for large deployments

```
Storage Savings
```

- **Similar Images**: 70-90% deduplication typical
- **Incremental Updates**: 95%+ deduplication common
- **Complete Rewrites**: Minimal deduplication

```
Integration Points
```

```
Deployment Pipeline
```

### op-deployment

```
Service Integration
```

- **op-plugins**: Deploy plugin binaries
- **op-services**: Deploy service configurations
- **op-tools**: Deployment automation scripts

```
Error Handling
```

```
Filesystem Errors
```

- Directory creation failures
- Permission issues
- BTRFS command failures

```
Deduplication Errors
```

- Hash calculation failures
- Symlink creation errors
- File copy failures

```
Recovery
```

- Partial images cleaned up on failure
- Atomic operations where possible
- Detailed error context via anyhow

```
Testing
```

## ### Test Coverage

- Unit tests for deduplication logic
- Integration tests with tempfile
- BTRFS detection tests
- Snapshot creation tests

## ### Test Utilities

#[cfg(test)]

#[tokio::test]

## ## Future Enhancements

- **Parallel Hashing**: Multi-threaded hash calculation
- **Hash Index**: Database for O(1) deduplication lookups
- **Compression**: Per-file compression for unique files
- **Remote Streaming**: Direct network streaming support
- **Garbage Collection**: Cleanup of unreferenced images
- **Incremental Snapshots**: BTRFS incremental send/receive
- **Multi-Backend**: Support for ZFS, LVM snapshots

## ## Security Considerations

- **Hash Verification**: SHA256 ensures file integrity
- **Symlink Safety**: Validate symlink targets within image
- **Permission Preservation**: Maintain file permissions in images
- **Atomic Operations**: Prevent partial deployments

Dependencies Comparison

Internal Workspace Dependencies
- `op-core` - documented in SPEC
- `op-tools` - documented in SPEC
- `op-execution-tracker` - documented in SPEC

External Runtime Dependencies
- `tokio` - documented in SPEC
- `serde` - documented in SPEC
- `simd-json` - documented in SPEC
- `chrono` - documented in SPEC
- `uuid` - documented in SPEC
- `thiserror` - documented in SPEC
- `tracing` - documented in SPEC
- `async-trait` - documented in SPEC
- `lru` - documented in SPEC
- `anyhow` - documented in SPEC
```

```
Development and Build Dependencies
- None

Notes and Observations

- Local documentation files present: SPEC.md.
- Root module declarations found in `lib.rs`/`main.rs`: dynamic_registry, error, execution_aware_loader, loading_strategy.

Current Implementation Overview

- MCP Gateway with WireGuard authentication and smart routing

Module / File Comparison

| Module or File | State | Current Role | Notes |
|---|---|---|---|

Feature / Capability Comparison

| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
- None

External Runtime Dependencies
- `tokio` - documented in SPEC
- `serde` - documented in SPEC
- `simd-json` - documented in SPEC
- `ring` - documented in SPEC
- `x25519-dalek` - documented in SPEC
- `chacha20poly1305` - documented in SPEC
```

```
- `argon2` - documented in SPEC
- `blake2` - documented in SPEC
- `zeroize` - documented in SPEC
- `base64` - documented in SPEC
- `hex` - documented in SPEC
- `sqlx` - documented in SPEC
- `tracing` - not listed in SPEC dependency block
- `uuid` - not listed in SPEC dependency block
- `thiserror` - not listed in SPEC dependency block
- `anyhow` - not listed in SPEC dependency block
- `chrono` - not listed in SPEC dependency block

Development and Build Dependencies
- None

Notes and Observations

- Local documentation files present: SECURITY-MODEL.md, SPEC.md.
- Root module declarations found in `lib.rs`/`main.rs`: encrypted_storage, error, mcp_gateway, wireguard_auth.
- 5 runtime dependencies are present in `Cargo.toml` but omitted from the SPEC dependency block.
</file>

<file path="op-gateway/SECURITY-MODEL.md">

DO NOT ROTATE WG PSK PER-LOGIN

WireGuard PSK has NO overlap mechanism. Rotating it locks you out.

Correct Model
```

WG PSK (STATIC - rarely rotated, manual only)

```
Rules

1. **PSK is identity** - treat like a certificate, not a password
2. **Server nonce prevents replay** - no timestamps, no clock drift
3. **Session keys rotate** - derived fresh each login
4. **simd-json at wire edge** - serde for config/internal

What Rotates vs What Doesn't

| Component | Rotates | How Often |
|-----|-----|-----|
| WG PSK | NO | Manual/yearly |
| Server Nonce | YES | Per-login |
| Session Key | YES | Per-login |
| Session ID | YES | Per-login |
| MCP Token | YES | Per-request or session |

Implementation

See `wireguard_auth.rs` - session derivation uses server nonce, not PSK rotation.

<file path="op-grpc-bridge/src/identity_sled_dispatch.rs">
 //!
 //! Executes the `identity_sled` plugin's method surface against the
 //! MutationEngine's authoritative state cache. Every call is already
 //! notarized in the immutable event chain by `dispatch_method_call` before it
 //! reaches here, so this module only performs the domain effect.
 //!
 //! Durability: sleds and the session-event "snowball" ledger persist to the
 //! never the users-cozo or cognitive-mcp store, which other processes hold
 //! open). The event chain remains the durable proof; Cozo is the queryable
 //! archive plus the restart-warm source for the state cache. All Cozo I/O is
 //! synchronous sled disk work, so it runs under `spawn_blocking`.
 //!
 //! creates the Incus instance (named by the derived session_id) and writes
 //!
 //! Compatibility: when the written identity is the host's own ("container
 //! zero"), the legacy raw sled at `/dev/shm/plugin_schema.dat` is also
 //! refreshed via `op_identity::schema_bridge::write_sled_from_wg`, because
 //! AnnaScribe still gates arrivals on that file. That projection goes away
 //! when AnnaScribe reads the sealed blob directly.

///
/// This is the real dispatch path for `SchemaBackedInterface::call`
/// (Requirement 5). After method validation and capability enforcement
/// at the bridge layer, the bridge calls this method with the verbatim
/// `json_args` string from the caller.
///
/// The method:
/// 1. Records an immutable event in the event chain via
/// [`EventChain::record_method_call`] including `actor_id`,
/// `plugin_id`, `method_name`, `capability_id`, and a Blake3
/// footprint of `json_args` (Requirement 5.5 / VAL-DISPATCH-005).
/// 2. The append occurs before the call returns success
/// (NFR-003 / VAL-NFR-003).
/// 3. Broadcasts the change to subscribers.
/// 4. Returns the result as a `serde_json::Value`.
///
/// Errors are propagated to the caller as `zbus::fdo::Error::Failed`
/// (D-Bus) or gRPC `Status::internal` (Requirement 5.3 /
/// VAL-DISPATCH-003) by the calling bridge interface.

<file path="op-grpc-bridge/src/zeroclaw_projection.rs">
 //! Zeroclaw projection hook (mission spec §9.2/§9.3, Phase 1b).
 //!
 //! Renders the **read-only** D-Bus sub-object tree for the Zeroclaw plugin:
 //! one managed object per declared `ModelRoute` at
 //! `/org/opdbus/v1/plugins/zeroclaw/routes/<hint>` and one per `Provider` at
 //! `/org/opdbus/v1/plugins/zeroclaw/providers/<id>`.
 //!
 //! # Dependency direction
 //! The mission text places the hook trait in `op-projection`, but `op-projection`
 //! already depends on `op-grpc-bridge` (not the reverse). Putting the trait there
 //! and implementing it here would create a crate cycle. The actual hard rule is
 //! "no crate cycle" (spec §10), so the trait lives here in `op-grpc-bridge` (which
 //! already depends on `op-plugins` for `ZeroclawState`). `op-projection` is
 //! untouched and the dependency graph stays acyclic.
 //!
 //! # No polling / watching / indexing
 //! `apply` is a synchronous push: the projection owner calls it after a cycle with
 //! the **in-memory** schema + state. There is no timer, no file watcher, and no
 //! `/dev/shm` re-read on this path. Property names are enumerated from

compare-op-grpc-bridge

Date: 2026-04-05
Spec files analyzed: SPEC.md
Analysis mode: Current system state specification with spec-alignment notes

Summary

| Category | Count |
|---|---|
| Rust source files | 8 |
| Proto files | 5 |
| Binary targets | 0 |
| UI files | 0 |
```

```
| Root-declared modules | 5 |
| Partial artifacts | 0 |
| Spec-listed source files | 6 |
| Spec-listed but missing | 0 |
| Extra implementation files | 2 |

Current Implementation Overview

- Bidirectional D-Bus <-> gRPC bridge with event chain integration
- Internal crate integrations: op-core, op-state-store, op-identity, op-network.
- Protocol assets: 5 ``.proto`` files.

Module / File Comparison

| Module or File | State | Current Role | Notes |
|---|---|---|---|

Feature / Capability Comparison

| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
- ``op-core`` - not listed in SPEC dependency block
- ``op-state-store`` - documented in SPEC
- ``op-identity`` - not listed in SPEC dependency block
- ``op-network`` - not listed in SPEC dependency block

External Runtime Dependencies
- ``tonic`` - documented in SPEC
- ``tonic-web`` - not listed in SPEC dependency block
- ``prost`` - documented in SPEC
- ``prost-types`` - documented in SPEC
- ``tonic-reflection`` - documented in SPEC
- ``tonic-health`` - not listed in SPEC dependency block
- ``tokio`` - documented in SPEC
- ``tokio-stream`` - documented in SPEC
- ``zbus`` - documented in SPEC
- ``serde`` - documented in SPEC
- ``serde_json`` - documented in SPEC
- ``simd-json`` - documented in SPEC
- ``tracing`` - not listed in SPEC dependency block
- ``anyhow`` - not listed in SPEC dependency block
- ``thiserror`` - not listed in SPEC dependency block
- ``async-trait`` - not listed in SPEC dependency block
- ``uuid`` - not listed in SPEC dependency block
- ``chrono`` - not listed in SPEC dependency block
- ``futures`` - not listed in SPEC dependency block
- ``async-stream`` - not listed in SPEC dependency block
- ``base64`` - not listed in SPEC dependency block

Development and Build Dependencies
- ``dev:tokio-test``
- ``build:tonic-build``

Notes and Observations

- Local documentation files present: SPEC.md.
- Current implementation contains 2 Rust source files beyond the explicit spec/design source inventory.
- Root module declarations found in ``lib.rs``/``main.rs``: dbus_watcher, grpc_client, grpc_server, proto_gen, schema_engine.
- RPC or protocol definition files: proto/mail.proto, proto/operation.proto, proto/privacy_network.proto, proto/registration.proto
- 14 runtime dependencies are present in ``Cargo.toml`` but omitted from the SPEC dependency block.
</file>

Spec files analyzed: SPEC.md
Analysis mode: Current system state specification with spec-alignment notes

Summary

| Category | Count |
|---|---|
| Rust source files | 8 |
| Proto files | 0 |
| Binary targets | 0 |
| UI files | 0 |
| Root-declared modules | 4 |
| Partial artifacts | 0 |
| Spec-listed source files | 8 |
| Spec-listed but missing | 0 |
| Extra implementation files | 0 |

Current Implementation Overview

- Central HTTP/TLS server for all op-dbus modules

Module / File Comparison

| Module or File | State | Current Role | Notes |
|---|---|---|---|

Feature / Capability Comparison

| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
- None

External Runtime Dependencies
- `tokio` - documented in SPEC
- `futures` - documented in SPEC
- `serde` - documented in SPEC
- `simd-json` - documented in SPEC
- `anyhow` - documented in SPEC
- `thiserror` - documented in SPEC
- `tracing` - documented in SPEC
- `axum` - documented in SPEC
- `tower` - documented in SPEC
- `tower-http` - documented in SPEC
- `hyper` - documented in SPEC
- `hyper-util` - not listed in SPEC dependency block
- `rustls` - not listed in SPEC dependency block
- `rustls-pemfile` - not listed in SPEC dependency block
- `tokio-rustls` - not listed in SPEC dependency block
- `chrono` - not listed in SPEC dependency block
- `gethostname` - not listed in SPEC dependency block

Development and Build Dependencies
- None

Notes and Observations

- Local documentation files present: SPEC.md.
- Root module declarations found in `lib.rs`/`main.rs`: middleware, router, server, tls.
- 6 runtime dependencies are present in `Cargo.toml` but omitted from the SPEC dependency block.

//! Generic CLI Introspection Adapter
//!
//! Generalizes the gcloud introspection pattern into a reusable framework
//! for ANY CLI program (incus, docker, kubectrl, helm, etc.).
//!
//! Handles both Go/cobra-style and Python/click-style help output formats,
//! as well as gcloud's ALL-CAPS section headers.
//!
//! # Usage
//!
//! ```rust,no_run
//! use op_inspector::cli::{CliParser, introspect_cli};
//!
//! // Quick introspection
//! let schema = introspect_cli("incus", 3).await?;
//!
//! // Custom help flag (e.g., for programs that use "-h" only)
//! let parser = CliParser::with_help_flag("mytool", "-h");
//! let schema = parser.introspect_full(2).await?;
//! ```

///! Introspective Gadget - Universal Object Inspector
///!
///!
///! This is the universal object inspector that can analyze ANY data structure
///! and add it to the knowledge base for schema generation and understanding.
///!
///! Examples:
///! - Docker containers: Inspect running containers, extract configurations
///! - XML data: Parse unknown XML structures, generate schemas
///! - JSON objects: Analyze complex nested structures
///! - Binary data: Attempt to reverse engineer structures
///! - Legacy formats: Handle old/obscure data formats (like Apple Lisa disks)
///!
///! The gadget can:
///! 1. Accept any input source (file, URL, data stream, etc.)
///! 2. Attempt multiple parsing strategies
///! 3. Extract structural information
///! 4. Generate validation schemas
///! 5. Add to knowledge base for future use
///! 6. Create templates for similar objects

Adapter Workflow: From Documentation to Integrated Tool

This document describes the workflow for creating an introspection adapter for any external system (gcloud, Active Directory, Dock

Overview

The workflow that was used for the gcloud adapter:

Step 1: Feed Documentation

Provide Claude with comprehensive documentation about the external system:

- **CLI tools**: Help output, man pages, reference documentation
- **APIs**: OpenAPI specs, SDK documentation, protocol specs
- **Services**: D-Bus introspection XML, LDAP schemas, etc.

For gcloud, Claude was given access to run `gcloud --help` recursively to discover the entire command hierarchy.

Step 2: Discover High-Level Surfaces

Before deep introspection, enumerate all introspectable entry points. This is the "table of contents" that tells you what exists t

Discovery Methods by System
```

```
| System | Discovery Command | What It Returns |
|-----|-----|-----|
| gcloud | `gcloud --help` | Top-level groups: compute, storage, container, iam, ... |

pubsub, recaptcha, recommender, redis, resource-manager,  
resource-settings, run, scc, scheduler, secrets,  
service-directory, services, source, spanner, sql,  
storage, tasks, telco-automation, topic, transcoder,  
transfer, vmware, workbench, workflows, workspace-add-ons, ...

This discovery step identifies ~100+ top-level groups, each of which will be recursively introspected in step 4.

### D-Bus Discovery Example

```
$ busctl --system list
```

```
org.freedesktop.Accounts
```

Each service is then introspected to discover its object paths, interfaces, methods, properties, and signals.

### Why Discovery Matters

1. **Scoping**: Know the full surface area before diving deep
2. **Incremental introspection**: Can introspect one group at a time
3. **Caching strategy**: Cache at the right granularity
4. **Progress tracking**: "Introspected 45/100 command groups"
5. **Schema design**: Informs what structures are needed

## Step 3: Design Schema Structures

Create Rust structs that capture the system's surface. Key patterns:

### Root Schema

```
#[derive(Debug, Clone, Serialize, Deserialize)]
```

### Hierarchical Items

```
#[derive(Debug, Clone, Serialize, Deserialize)]
```

### Parameters/Flags

```
#[derive(Debug, Clone, Serialize, Deserialize)]
```

## Step 4: Implement Parser

Create a parser that implements `ObjectParser` trait:

```
pub struct GCloudParser {
```

```
#[async_trait]
```

### Introspection Strategy

For gcloud, the parser:

1. Runs `gcloud [command\_path] --help`

Ret

## OP-DBUS / BigPickle

2. Parses the help text with regex to extract:
3. Recursively introspects subcommands up to `max_depth`
4. Caches results to avoid redundant calls

```
async fn introspect_command(

let groups = self.parse_groups(&help);

// Recursively introspect children

Ok(cmd)
```

## Step 5: Create Tools (Integration Gap)

This is where gcloud integration is incomplete. Need to create tools in ``op-tools/src/builtin/gcloud_tools.rs``:

```
pub async fn register_gcloud_tools(registry: &ToolRegistry) -> Result<()> {

registry.register_tool(Arc::new(GCloudIntrospectTool::new(parser.clone()))).await?;

Ok(())

struct GCloudIntrospectTool {

#[async_trait]

fn description(&self) -> &str {

fn input_schema(&self) -> Value {

async fn execute(&self, input: Value) -> Result<Value> {
```

## Step 6: Register Tools

Add to ``op-tools/src/builtin/mod.rs``:

```
pub mod gcloud_tools;

pub async fn register_all_builtin_tools(registry: &ToolRegistry) -> Result<()> {

// Register gcloud tools

Ok(())
```

## Applying to Other Systems

### Active Directory / LDAP

```
pub struct LdapSchema {

pub struct LdapParser {
```

### Docker

```
pub struct DockerSchema {

pub struct DockerParser {
```

### D-Bus (Already Done)

The D-Bus adapter in ``op-introspection`` follows this same pattern:

- ``IntrospectionService`` - the parser
- ``ServiceScanner`` - runs introspection
- ``dbus_introspection.rs`` - the tools (12 tools registered)

## File Locations

crates/

## Summary

Step	gcloud Status	D-Bus Status
-----	-----	-----
1. Documentation	Fed to Claude	Built-in introspection
3. Schema structs	`GCloudSchema`, `GCloudCommand`, etc.	`ObjectInfo`, `InterfaceInfo`, etc.
4. Parser	`GCloudParser`	`IntrospectionService`
5. Tools	**Missing**   12 tools in `dbus_introspection.rs`	
6. Registration	**Missing**   In `register_all_builtin_tools()`	

The gcloud adapter is complete through step 4. Steps 5-6 need implementation to make it available to agents through the tool system

## Current Implementation Overview

- Inspector Gadget - Universal object inspector with AI gap-filling and Proxmox introspection
- Internal crate integrations: op-core, op-introspection.

## Module / File Comparison

Module or File	State	Current Role	Notes
---	---	---	---

## Feature / Capability Comparison

```
| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
- `op-core` - documented in SPEC
- `op-introspection` - documented in SPEC

External Runtime Dependencies
- `tokio` - documented in SPEC
- `serde` - documented in SPEC
- `simd-json` - documented in SPEC
- `anyhow` - documented in SPEC
- `thiserror` - documented in SPEC
- `tracing` - documented in SPEC
- `async-trait` - documented in SPEC
- `uuid` - documented in SPEC
- `chrono` - documented in SPEC
- `regex` - documented in SPEC
- `quick-xml` - documented in SPEC
- `sha2` - documented in SPEC
- `base64` - documented in SPEC
- `serde_yaml` - documented in SPEC

Development and Build Dependencies
- None

Notes and Observations

- Local documentation files present: ADAPTER-WORKFLOW.md, SPEC.md.
- Current implementation contains 1 Rust source files beyond the explicit spec/design source inventory.
- Root module declarations found in `lib.rs`/`main.rs`: gcloud, introspective_gadget.

Spec files analyzed: SPEC.md
Analysis mode: Current system state specification with spec-alignment notes

Summary

| Category | Count |
|---|---|
| Rust source files | 10 |
| Proto files | 0 |
| Binary targets | 0 |
| UI files | 0 |
| Root-declared modules | 6 |
| Partial artifacts | 0 |
| Spec-listed source files | 10 |
| Spec-listed but missing | 0 |
| Extra implementation files | 0 |

Current Implementation Overview

- Dbus introspection capabilities for op-dbus-v2
- Internal crate integrations: op-core, op-blockchain.

Module / File Comparison

| Module or File | State | Current Role | Notes |
|---|---|---|---|

Feature / Capability Comparison

| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
- `op-core` - documented in SPEC
- `op-blockchain` - documented in SPEC

External Runtime Dependencies
- `tokio` - documented in SPEC
- `serde` - documented in SPEC
- `simd-json` - documented in SPEC
- `zbus` - documented in SPEC
- `zbus_xml` - documented in SPEC
- `anyhow` - documented in SPEC
- `thiserror` - documented in SPEC
- `tracing` - documented in SPEC
- `futures` - documented in SPEC
- `async-trait` - documented in SPEC
- `quick-xml` - documented in SPEC
- `rusqlite` - documented in SPEC
- `chrono` - documented in SPEC
- `parking_lot` - documented in SPEC
- `sha2` - documented in SPEC
- `hex` - documented in SPEC

Development and Build Dependencies
- None

Notes and Observations

- Local documentation files present: SPEC.md.
- Root module declarations found in `lib.rs`/`main.rs`: cache, indexer, indexer_manager, parser, projection, scanner.
</file>

Spec files analyzed: SPEC.md
Analysis mode: Current system state specification with spec-alignment notes

Summary

| Category | Count |
|---|---|
| Rust source files | 8 |
| Proto files | 0 |
| Binary targets | 0 |
| UI files | 0 |
| Root-declared modules | 4 |
| Partial artifacts | 0 |
| Spec-listed source files | 0 |
| Spec-listed but missing | 0 |
| Extra implementation files | 8 |

Current Implementation Overview

- JSON-RPC server with OVSDB and NonNet database support for op-dbus-v2
- Internal crate integrations: op-core.

Module / File Comparison

| Module or File | State | Current Role | Notes |
|---|---|---|---|

Feature / Capability Comparison

| Capability | State | Evidence | Source |
|---|---|---|---|

Dependencies Comparison

Internal Workspace Dependencies
- `op-core` - not listed in SPEC dependency block

External Runtime Dependencies
- `tokio` - not listed in SPEC dependency block
- `serde` - not listed in SPEC dependency block
- `simd-json` - not listed in SPEC dependency block
- `anyhow` - not listed in SPEC dependency block
- `thiserror` - not listed in SPEC dependency block
- `tracing` - not listed in SPEC dependency block
- `uuid` - not listed in SPEC dependency block

Development and Build Dependencies
```

```
- None

Notes and Observations

- Local documentation files present: SPEC.md.
- Current implementation contains 8 Rust source files beyond the explicit spec/design source inventory.
- Root module declarations found in `lib.rs`/`main.rs`: nonnet, ovsdb, protocol, server.
</file>

<file path="op-jsonrpc/SPEC.md">
op-jsonrpc - Specification

Overview
Crate: `op-jsonrpc`
Location: `crates/op-jsonrpc`
Description: JSON-RPC server with OVSDB and NonNet database support for op-dbus-v2

Purpose

The `op-jsonrpc` crate provides a comprehensive JSON-RPC 2.0 server implementation with specialized support for Open vSwitch Datab

- **JSON-RPC 2.0 Protocol**: Standards-compliant RPC server over Unix sockets
- **OVSDb Integration**: Client for Open vSwitch database operations
- **NonNet Database**: State management for non-network plugins
- **Async Operations**: Non-blocking I/O with tokio runtime

This crate is essential for:
- Plugin communication via JSON-RPC
- Network configuration through OVSDB
- State persistence for non-network components
- Inter-process communication within operation-dbus

Architecture

Protocol Layer
Implements JSON-RPC 2.0 specification:
- Request/response message types
- Error handling with standard error codes
- Batch request support
- Notification messages (no response expected)

Server Layer
Unix socket-based JSON-RPC server:
- Async request handling
- Method routing and dispatch
- Connection management
- Error recovery

Database Integrations

OVSDB Client
Connects to Open vSwitch database for network operations:
- Schema introspection
- Transactional operations
- Monitor/update subscriptions
- Bridge and port management

NonNet Database
Custom database for non-network plugin state:
- Key-value storage
- Plugin configuration persistence
- State synchronization
- Query and update operations

Key Components

JsonRpcRequest
Represents a JSON-RPC 2.0 request.
```

```
pub struct JsonRpcRequest {
```

```
 Constructors:
```

## OP-DBUS / BigPickle

// Create with auto-generated ID

// Create with specific ID

```
JsonRpcResponse
Represents a JSON-RPC 2.0 response.
```

```
pub struct JsonRpcResponse {
```

```
 Constructors:
```

// Success response

// Error response
